

Global Illumination and Radiosity

CS434

Daniel G. Aliaga
Department of Computer Science
Purdue University

Recall: Lighting and Shading

- Light sources
 - Point light
 - Models an omnidirectional light source (e.g., a bulb)
 - Directional light
 - Models an omnidirectional light source at infinity
 - Spot light
 - Models a point light with direction
- Light model
 - Ambient light
 - Diffuse reflection
 - Specular reflection

Recall: Lighting and Shading

- Diffuse reflection
 - Lambertian model

$$I_D = K_D(N \cdot L)I_L$$

Recall: Lighting and Shading

- Specular reflection
 - Phong model

$$I_S = K_S (V \cdot R)^n I_L$$

Global Illumination

- Consider *direct illumination* as well as *indirect illumination*; e.g.
 - Reflections, refractions, shadows, etc.
 - Diffuse inter-reflection

direct illumination

with global illumination

only diffuse inter-reflection

Global Illumination

- Consider *direct illumination* as well as *indirect illumination*; e.g.
 - Reflections, refractions, shadows, etc.
 - Diffuse inter-reflection, specular inter-reflection, etc.

Radiosity

- Radiosity, inspired by ideas from heat transfer, is an application of a finite element method to solving the rendering equation for scenes with purely diffuse surfaces

$$L_o(\mathbf{x}, \omega, \lambda, t) = L_e(\mathbf{x}, \omega, \lambda, t) + \int_{\Omega} f_r(\mathbf{x}, \omega', \omega, \lambda, t) L_i(\mathbf{x}, \omega', \lambda, t) (-\omega' \cdot \mathbf{n}) d\omega'$$

(rendering equation)

Radiosity

- Equation: $B_i dA_i = E_i dA_i + R_i \int_j B_j F_{ji} dA_j$

(more details on the board...)

Radiosity

U. Of Calgary

Radiosity

- Calculating the overall light propagation within a scene, for short **global illumination** is a very difficult problem.
- With a standard ray tracing algorithm, this is a very time consuming task, since a huge number of rays have to be shot.

Global Illumination?

Radiosity

- For this reason, the radiosity method was invented.

- The main idea of the method is

to store illumination values on the surfaces of the objects, as the light is propagated starting at the light sources.

■ Diffuse Interreflection

Diffuse Interreflection

- Surface = "diffuse reflector" of light energy,
- means: any light energy which strikes the surface will be reflected in all directions,
- dependent only on the angle between the surface's normal and the incoming light vector (Lambert's law).

Diffuse Interreflection

- The reflected light energy often is colored, to some small extent, by the color of the surface from which it was reflected.

- This reflection of light energy in an environment produces a phenomenon known as "color bleeding," where a brightly colored surface's color will "bleed" onto adjacent surfaces.

Diffuse Interreflection

- The reflected light energy often is colored, to some small extent, by the color of the surface from which it was reflected.

“Color bleeding”, as both the red and blue walls “bleed” their color onto the white walls, ceiling and floor.

Radiosity (Thermal Heat Transfer)

- The "radiosity" method has its basis in the field of thermal heat transfer.
- Heat transfer theory describes radiation as the transfer of energy from a surface when that surface has been thermally excited.

- This encompasses both **surfaces** which are basic **emitters of energy**, as with light sources, and surfaces which receive energy from other surfaces and thus have energy to transfer.
- This "thermal radiation" theory can be used to describe the transfer of many kinds of energy between surfaces, including light energy.

Radiosity (Computer Graphics)

- Assumption #1: surfaces are diffuse emitters and reflectors of energy, emitting and reflecting energy uniformly over their entire area.
- Assumption #2: an equilibrium solution can be reached; that all of the energy in an environment is accounted for, through absorption and reflection.
- Also viewpoint independent: the solution will be the same regardless of the viewpoint of the image.

The Radiosity Equation

- The "radiosity equation" describes the **amount of energy** which can be emitted from a surface, as the sum of the energy inherent in the surface (a light source, for example) and the energy which strikes the surface, being emitted from some other surface.
- The energy which leaves a surface (surface "j") and strikes another surface (surface "i") is attenuated by two factors:
 - the **"form factor"** between surfaces "i" and "j", which accounts for the physical relationship between the two surfaces
 - the **reflectivity of surface "i"**, which will absorb a certain percentage of light energy which strikes the surface.

The Radiosity Equation

■ The Radiosity Equation

$$B_i = \boxed{E_i} + \rho_i \sum B_j F_{ij}$$

■ **Energy emitted** by surface i

■ The Radiosity Equation

$$B_i = E_i + \rho_i \sum B_j F_{ij}$$

■ **Energy reaching** surface i from other surfaces

■ The Radiosity Equation

$$B_i = E_i + \rho_i \sum B_j F_{ij}$$

■ **Energy reflected** by surface i

Radiosity

- **Classic radiosity = finite element method**
- **Assumptions**
 - Diffuse reflectance
 - Usually polygonal surfaces
- **Advantages**
 - Soft shadows and indirect lighting
 - View independent solution
 - Precompute for a set of light sources
 - Useful for walkthroughs

Display Solution

The Form Factor:

The fraction of energy leaving one surface that reaches another surface

It is a purely geometric relationship,
independent of viewpoint or surface attributes

- Between differential areas, the form factor equals:

differential area of surface i, j

angle between Normal_i and r

angle between Normal_j and r

$$F dA_i dA_j = \frac{\cos \theta_i \cos \theta_j}{\pi |r|^2}$$

vector from dA_i to dA_j

Between differential areas, the form factor equals:

$$FdA_j dA_j = \frac{\cos \theta_i \cos \theta_j}{\pi |r|^2}$$

The overall form factor between i and j is found by integrating

$$F_{ij} = \frac{1}{A_i} \int_{A_i} \int_{A_j} \frac{\cos \theta_i \cos \theta_j}{\pi |r|^2} dA_i dA_j$$

Next Step:

Learn ways of computing **form factors**

- Recall the Radiosity Equation:

$$B_i = E_i + \rho_i \sum B_j F_{ij}$$

- The F_{ij} are the form factors
- Form factors independent of radiosities
(depend only on scene geometry)

Form Factors in (More) Detail

$$F_{ij} = \frac{1}{A_i} \int_{A_i} \int_{A_j} \frac{\cos \theta_i \cos \theta_j}{\pi |r|^2} dA_i dA_j$$

$$F_{ij} = \frac{1}{A_i} \int_{A_i} \int_{A_j} \frac{\cos \theta_i \cos \theta_j}{\pi |r|^2} V_{ij} dA_i dA_j$$

where V_{ij} is the visibility (0 or 1)

We have two integrals to compute:

$$F_{ij} = \frac{1}{A_i} \int_{A_i} \int_{A_j} \frac{\cos \theta_i \cos \theta_j}{\pi r^2} V_{ij} dA_j dA_i$$

Area integral

Area integral
over surface *j*

The Nusselt Analog

- Differentiation of the basic form factor equation is difficult even for simple surfaces!
- Nusselt developed a geometric analog which allows the simple and accurate calculation of the form factor between a surface and a point on a second surface.

The Nusselt Analog

- The "Nusselt analog" involves placing a hemispherical projection body, with unit radius, at a point on a surface.
- The second surface is spherically projected onto the projection body, then cylindrically projected onto the base of the hemisphere.
- The form factor is, then, the area projected on the base of the hemisphere divided by the area of the base of the hemisphere.

Numerical Integration: The Nusselt Analog

This gives the form factor $F_{dA_i A_j}$

Figure 4.8: Nusselt analog. The form factor from the differential area dA_i to element A_j is proportional to the area of the double projection onto the base of the hemisphere.

The Nusselt Analog

1. Project A_j along its normal
 $A_j \cos q_j$
2. Project result on sphere:
 $A_j \cos q_j / r^2$
3. Project result on unit circle:
 $A_j \cos q_j \cos q_i / r^2$
4. Divide by unit circle area:
 $A_j \cos q_j \cos q_i / \pi r^2$
5. Integrate for all points on A_j :

$$F_{dA_i A_j} = \int_{A_j} \frac{\cos \theta_i \cos \theta_j}{\pi r^2} V_{ij} dA_j$$

Method 1: Hemicube

- Approximation of Nusselt's analog between a point dA_i and a polygon A_j

Hemicube

- For convenience, a cube 1 unit high with a top face 2×2 is used. Side faces are 2 wide by 1 high.
- Decide on a resolution for the cube.
Say 512 by 512 for the top.

The Hemicube In Action

The Hemicube In Action

The Hemicube In Action

- This illustration demonstrates the calculation of form factors between a particular surface on the wall of a room and several surfaces of objects in the room.

Compute the form factors from a point on a surface to all other surfaces by:

- Projecting all other surfaces onto the hemicube
- Storing, at each discrete area, the identifying index of the surface that is closest to the point.

Discrete areas with the indices of the surfaces which are ultimately visible to the point.

From there the form factors between the point and the surfaces are calculated.

For greater accuracy, a large surface would typically be broken into a set of small surfaces before any form factor calculation is performed.

Hemicube Method

1. Scan convert all scene objects onto hemicube's 5 faces
2. Use Z buffer to determine visibility term
3. Sum up the delta form factors of the hemicube cells covered by scanned objects
4. Gives form factors from hemicube's base to all elements,
i.e. F_{dAiAj} for given i and all j

Hemicube Algorithms

Advantages

- + First practical method
- + Use existing rendering systems; Hardware
- + Computes row of form factors in $O(n)$

Disadvantages

- Computes differential-finite form factor
- Aliasing errors due to sampling
 - Randomly rotate/shear hemicube*
- Proximity errors
- Visibility errors
- Expensive to compute a single form factor

Method 2: Area Sampling

Subdivide A_j into small pieces dA_j

For all dA_j

cast ray dA_i - dA_j to determine V_{ij}

if visible

compute $F_{dA_i dA_j}$

$$F_{dA_i dA_j} = \frac{\cos \theta_i \cos \theta_j}{\pi r^2} V_{ij} dA_j$$

sum up

$$F_{dA_i A_j} += F_{dA_i dA_j}$$

We have now $F_{dA_i A_j}$

Summary

- Several ways to find form factors
- **Hemicube** was original method
 - + Hardware acceleration
 - + Gives F_{dAiAj} for all j in one pass
 - Aliasing
- **Area sampling** methods now preferred
 - Slower than hemicube
 - As accurate as desired since adaptive

Next

- We have the form factors
- How do we find the radiosity solution for the scene?
 - The "Full Matrix" Radiosity Algorithm
 - Gathering & Shooting
 - Progressive Radiosity
- Meshing

Radiosity Matrix

$$B_i = E_i + \rho_i \sum_{j=1}^n F_{ij} B_j$$

$$B_i - \rho_i \sum_{j=1}^n F_{ij} B_j = E_i$$

$$\begin{bmatrix} 1 - \rho_1 F_{11} & -\rho_1 F_{12} & \cdots & -\rho_1 F_{1n} \\ -\rho_2 F_{21} & 1 - \rho_2 F_{22} & \cdots & -\rho_2 F_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ -\rho_n F_{n1} & -\rho_n F_{n2} & \cdots & 1 - \rho_n F_{nn} \end{bmatrix} \begin{bmatrix} B_1 \\ B_2 \\ \vdots \\ B_n \end{bmatrix} = \begin{bmatrix} E_1 \\ E_2 \\ \vdots \\ E_n \end{bmatrix}$$

Radiosity Matrix

- The "full matrix" radiosity solution calculates the form factors between each pair of surfaces in the environment, then forms a series of simultaneous linear equations.

$$\begin{bmatrix} 1 - \rho_1 F_{11} & -\rho_1 F_{12} & \cdots & -\rho_1 F_{1n} \\ -\rho_2 F_{21} & 1 - \rho_2 F_{22} & \cdots & -\rho_2 F_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ -\rho_n F_{n1} & -\rho_n F_{n2} & \cdots & 1 - \rho_n F_{nn} \end{bmatrix} \begin{bmatrix} B_1 \\ B_2 \\ \vdots \\ B_n \end{bmatrix} = \begin{bmatrix} E_1 \\ E_2 \\ \vdots \\ E_n \end{bmatrix}$$

- This matrix equation is solved for the "B" values, which can be used as the final intensity (or color) value of each surface.

Radiosity Matrix

- This method produces a complete solution, at the substantial cost of
 - first calculating form factors between each pair of surfaces
 - and then the solution of the matrix equation.
- This leads to substantial costs not only in computation time but in storage.

Shooting

SHOOTING

- Shooting light through a single hemi-cube allows the whole environment's radiosity values to be updated simultaneously.

$$\begin{bmatrix} x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \end{bmatrix} = \begin{bmatrix} x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \end{bmatrix} + \begin{bmatrix} x \end{bmatrix} \begin{bmatrix} x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \\ x \end{bmatrix}$$

Four red arrows point from the four vector terms in the equation to the radiosity update formula below.

$$\text{For all } j \implies B_j = B_j + B_i (\rho_j E_{ji})$$

$$\text{where } F_{ji} = \frac{F_{ij} A_i}{A_j}$$

Shooting

```
for(i=0; i<n; i++) {  
    B[i] = dB[i] = Be[i];  
    while( !converged ) {  
        set i st dB[i] is the largest;  
        for(j=0; j<n; j++)  
            if(i!=j) {  
                db =rho[j]*F[j][i]*dB[i];  
                dB[j] += db;  
                B[j] += db;  
            }  
        dB[i]=0;  
    }  
}
```

Some Radiosity Results

The Cornell Box

- This is the original Cornell box, as simulated by Cindy M. Goral, Kenneth E. Torrance, and Donald P. Greenberg for the 1984 paper *Modeling the interaction of Light Between Diffuse Surfaces*, Computer Graphics (SIGGRAPH '84 Proceedings), Vol. 18, No. 3, July 1984, pp. 213-222.
- Because form factors were computed analytically, no occluding objects were included inside the box.

The Cornell Box

- This simulation of the Cornell box was done by Michael F. Cohen and Donald P. Greenberg for the 1985 paper *The Hemi-Cube, A Radiosity Solution for Complex Environments*, Vol. 19, No. 3, July 1985, pp. 31-40.
- The hemi-cube allowed form factors to be calculated using scan conversion algorithms (which were available in hardware), and made it possible to calculate shadows from occluding objects.

Discontinuity Meshing

Opera Lighting

- This scene from *La Boheme* demonstrates the use of focused lighting and angular projection of predistorted images for the background.
- It was rendered by Julie O'B. Dorsey, Francois X. Sillion, and Donald P. Greenberg for the 1991 paper *Design and Simulation of Opera Lighting and Projection Effects*.

Radiosity Factory

- These two images were rendered by Michael F. Cohen, Shenchang Eric Chen, John R. Wallace and Donald P. Greenberg for the 1988 paper *A Progressive Refinement Approach to Fast Radiosity Image Generation*.
- The factory model contains 30,000 patches, and was the most complex radiosity solution computed at that time.
- The radiosity solution took approximately 5 hours for 2,000 shots, and the image generation required 190 hours; each on a VAX8700.

Museum

- Most of the illumination that comes into this simulated museum arrives via the baffles on the ceiling.
- As the progressive radiosity solution executed, users could witness each of the baffles being illuminated from above, and then reflecting some of this light to the bottom of an adjacent baffle.
- A portion of this reflected light was eventually bounced down into the room.
- The image appeared on the proceedings cover of SIGGRAPH 1988.
