Deadlock

- A transaction is deadlocked if it is blocked and will remain blocked until there is intervention.
- Locking-based CC algorithms may cause deadlocks.
- TO-based algorithms that involve waiting may cause deadlocks.
- Wait-for graph
  - If transaction $T_i$ waits for another transaction $T_j$ to release a lock on an entity, then $T_i \rightarrow T_j$ in WFG.
Local versus Global WFG

Assume $T_1$ and $T_2$ run at site 1, $T_3$ and $T_4$ run at site 2. Also assume $T_3$ waits for a lock held by $T_4$ which waits for a lock held by $T_1$ which waits for a lock held by $T_2$ which, in turn, waits for a lock held by $T_3$.

Local WFG

<table>
<thead>
<tr>
<th>Site 1</th>
<th>Site 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>$T_1$</td>
<td>$T_4$</td>
</tr>
<tr>
<td>$T_2$</td>
<td>$T_3$</td>
</tr>
</tbody>
</table>

Global WFG

<table>
<thead>
<tr>
<th>Site 1</th>
<th>Site 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>$T_1$</td>
<td>$T_4$</td>
</tr>
<tr>
<td>$T_2$</td>
<td>$T_3$</td>
</tr>
</tbody>
</table>
Deadlock Management

- Ignore
  - Let the application programmer deal with it, or restart the system

- Prevention
  - Guaranteeing that deadlocks can never occur in the first place. Check transaction when it is initiated. Requires no run time support.

- Avoidance
  - Detecting potential deadlocks in advance and taking action to insure that deadlock will not occur. Requires run time support.

- Detection and Recovery
  - Allowing deadlocks to form and then finding and breaking them. As in the avoidance scheme, this requires run time support.
Deadlock Prevention

- All resources which may be needed by a transaction must be predeclared.
  - The system must guarantee that none of the resources will be needed by an ongoing transaction.
  - Resources must only be reserved, but not necessarily allocated a priori
  - Unsuitability of the scheme in database environment
  - Suitable for systems that have no provisions for undoing processes.

- Evaluation:
  - Reduced concurrency due to preallocation
  - Evaluating whether an allocation is safe leads to added overhead.
  - Difficult to determine (partial order)
  + No transaction rollback or restart is involved.
Deadlock Avoidance

- Transactions are not required to request resources a priori.
- Transactions are allowed to proceed unless a requested resource is unavailable.
- In case of conflict, transactions may be allowed to wait for a fixed time interval.
- Order either the data items or the sites and always request locks in that order.
- More attractive than prevention in a database environment.
Deadlock Avoidance –
Wait-Die & Wound-Wait Algorithms

**WAIT-DIE Rule:** If \( T_i \) requests a lock on a data item which is already locked by \( T_j \), then \( T_i \) is permitted to wait iff \( ts(T_i) < ts(T_j) \). If \( ts(T_i) > ts(T_j) \), then \( T_i \) is aborted and restarted with the same timestamp.

- if \( ts(T_i) < ts(T_j) \) then \( T_i \) waits else \( T_i \) dies
- non-preemptive: \( T_i \) never preempts \( T_j \)
- prefers younger transactions

**WOUND-WAIT Rule:** If \( T_i \) requests a lock on a data item which is already locked by \( T_j \), then \( T_i \) is permitted to wait iff \( ts(T_i) > ts(T_j) \). If \( ts(T_i) < ts(T_j) \), then \( T_j \) is aborted and the lock is granted to \( T_i \).

- if \( ts(T_i) < ts(T_j) \) then \( T_j \) is wounded else \( T_i \) waits
- preemptive: \( T_i \) preempts \( T_j \) if it is younger
- prefers older transactions
Transactions are allowed to wait freely.

- Wait-for graphs and cycles.
- Topologies for deadlock detection algorithms
  - Centralized
  - Distributed
  - Hierarchical
Centralized Deadlock Detection

One site is designated as the deadlock detector for the system. Each scheduler periodically sends its local WFG to the central site which merges them to a global WFG to determine cycles.

How often to transmit?

- Too often ⇒ higher communication cost but lower delays due to undetected deadlocks
- Too late ⇒ higher delays due to deadlocks, but lower communication cost

Would be a reasonable choice if the concurrency control algorithm is also centralized.

Proposed for Distributed INGRES
Hierarchical Deadlock Detection

Build a hierarchy of detectors

Site 4
Distributed Deadlock Detection

- Sites cooperate in detection of deadlocks.

- One example:
  - The local WFGs are formed at each site and passed on to other sites. Each local WFG is modified as follows:
    - Since each site receives the potential deadlock cycles from other sites, these edges are added to the local WFGs.
    - The edges in the local WFG which show that local transactions are waiting for transactions at other sites are joined with edges in the local WFGs which show that remote transactions are waiting for local ones.
  - Each local deadlock detector:
    - looks for a cycle that does not involve the external edge. If it exists, there is a local deadlock which can be handled locally.
    - looks for a cycle involving the external edge. If it exists, it indicates a potential global deadlock. Pass on the information to the next site.
