Homework 1 Solution

Elisha Sacks

Problem 1: Circle Through Three Points

- ► The perpendicular bisector of ab is p + ku with p = (a + b)/2 and u = (b_y - a_y, a_x - b_x).
- Likewise, q + lv for bc.
- The center o is the intersection point of the bisectors.
- Solve $(p + ku q) \times v = 0$ for $k = (q p) \times v/u \times v$.
- If the points are collinear, $u \times v = 0$ and there is no solution.

Problem 1: ACP Code

class CircleCenter : public Point {
 Point *a, *b, *c;

```
DeclareCalculate (PV2) {
     PV2 \ll N > aa = a \rightarrow get \ll N > ()
             bb = b \rightarrow get \langle N \rangle
              cc = c \rightarrow get \langle N \rangle
             p = (aa + bb)/2, q = (bb + cc)/2,
             u(bb.y - aa.y, aa.x - bb.x),
             v(cc.y - bb.y, bb.x - cc.x);
    N k = (q - p).cross(v)/u.cross(v);
     return p + k*u;
  }
public :
  CircleCenter (Point *a, Point *b, Point *c)
     : a(a), b(b), c(c) {}
};
```

Problem 2: Ray/Line Segment Intersection

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

When does the ray a + ku intersect the line segment pq?

Problem 2: Ray/Line Segment Intersection

イロト イロト イヨト イヨト 三日

When does the ray a + ku intersect the line segment pq? 1. p and q are on opposite sides of a + ku.

Problem 2: Ray/Line Segment Intersection

When does the ray a + ku intersect the line segment pq?

1. p and q are on opposite sides of a + ku.

2. *a* is on one side of *pq* and *u* points into the other side. How are these tests performed?

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

1.
$$\operatorname{sign}(u \times (p-a)) \neq \operatorname{sign}(u \times (q-a))$$

2. $\operatorname{sign}((a-p)\times(q-p))\neq\operatorname{sign}(u\times(q-p))$

Problem 3: Circle/Line Segment Intersection

- The distance from o to the ab line is less than r: $-r < \frac{n}{||n||} \cdot (o-a) < r$ with $n = (b_x - a_x, a_y - b_y)$.
- Squaring yields $(n \cdot (o a))^2 < (n \cdot n)r^2$.
- Points a and b are outside the circle: (a − o) · (a − o) > r² and (b − o) · (b − o) > r².
- Points a and b are on opposite sides of the line through o and tangent to n: sign(n × (a − o)) = −sign(n × (b − o)).

Problem 4: 3D Triangle Intersection

Two triangles intersect when an edge of one intersects the interior of the other.

An edge *ef* intersects a triangle *abc* when the intersection point of *ef* with the *abc* plane is inside *abc*.

The intersection point, p = e + ku with u = f - e, satisfies $n \cdot (e + ku - a) = 0$ with $n = (a - b) \times (a - c)$. It lies on *ef* when 0 < k < 1.

Let p' be the projection of p onto the coordinate plane of the largest magnitude component of n, e.g. $p' = (p_x, p_y)$ when $|n_z|$ is largest. Apply the 2D point-in-triangle test LT(a', b', p') > 0, LT(b', c', p') > 0, and LT(c', a', p') > 0.

- 1. ef intersects an abc edge: one of the LT is zero.
- 2. ef contains an abc vertex: two of the LT are zero.
- 3. e or f is in abc: k = 0 or k = 1.
- 4. e or f is on an abc edge: tests 1 and 3.
- 5. e or f is an abc vertex: tests 2 and 3.
- 6. *e* and *f* are in the *abc* plane: $n \cdot u = 0$, project and compute 2D edge/edge intersections.
