Lecture 26

Explicit methods.
Local truncation error.
Consistency.

Then more on error and how we'll study global error!

HW5
a) Due: April 30 to be graded before final
b) Otherwise May 1st (Tuesday!) but not graded before final)

ODEs, IVPs

$\frac{dy}{dt} = f(t,y)$

$y(t_0) = y_0$ given.

Study Euler!
Need to understand method!

For the moment, we'll use **explicit methods** those that do not depend on solving systems of equations such as the Backward or Implicit methods.

In general, a one-step method is

$$y_{n+1} = y_n + h\Phi(t_n, y_n, h).$$

Which we'll also write as:

$$y_+ = y + h\Phi(t, y, h)$$

Omitted the index i and make it slightly more general.
The explicit Euler: $\Phi = f(t, y)$.
The idea with Φ is that we should locally approximate the initial value problem.

$\Phi(t, y, h) \approx \frac{dy}{dt} = f(t, y)$ is the "method".

Case: $\Phi(t, y; h) = f(t, y)$ from Euler

$\Phi(t, y; h) - \frac{1}{2} f(t, y) + \frac{1}{2} f(t+h, y + h f(y))$

2 types of error
- Local → is the method Reasonable
- Global → is the answer "right"?

Local analysis is what we'll expand to

$u(t) = y$ (that same)
Exists for $t \in [a, b]$

Now it's time to talk error! Here, we'll use $u(\cdot)$ as the reference solution. We want to get as close as possible to this!

DEFINITION. *The truncation error of the method Φ with respect to u is:*

$$T(t, y; h) = \frac{1}{h}(u(t+h) - u(t)) - \Phi(t, y, h)$$

Q: When is Φ ??? Reasonable

$y_+ = y + h\Phi(t, y; h)$

$T(t, y; h) = \frac{1}{h}(u(t+h) - u(t)) - \Phi(t, y, h)$

(where did y go?? $y = u(t)$!)

To show:
Local class
Φ look
like the derivative
$\frac{1}{h}(u(t+h) - u(t))$?

$u(t) = y$

$T(t, y; h) \to 0 \Rightarrow$

$\Phi(t, y; h) = \frac{1}{h}(u(t+h) - u(t)) \to 0$
$\lim_{h \to 0} \Phi(t, y; h) = f(t, y)$
by Continuity

A method is **consistent** if $T(t, y; h) \to 0$ as $h \to 0$ for all t, y in some domain, uniformly.

Consistency is equivalent to $\Phi(t, y; 0) = f(t, y)$.

Consistency is called from Smoothness of f is called from Smoothness of u

A method has *order* p if (for some vector norm) $\|T(t, y; h)\| \le Ch^p$ for some constant.

Example:

Forward Euler

$\Phi(t, y; h) = f(t, y)$

So

$\lim_{h \to 0} \Phi(t, y; h) = f(t, y)$

Local method!
$\Rightarrow$ Consistent!

Becomes $\Phi(t, y; 0) = f(t, y)$

How to Establish order? Info coming in 1. See textbook.

Taylor Extrapolation

Idea: Use more
derivative from Taylor's
Theorem

$y(t+h) = y(t) + h y'(t) + \frac{h^2}{2!} y''(t) + \frac{h^3}{3!} y'''(t) + O(h^4)$

$\Rightarrow$ Turn this into a method by approximating derivatives of $y(t, y)$

$\Phi(t, y; h) = f(t, y) + \frac{h}{2} y'(t, y) + \frac{h^2}{3!} y''(t, y)$

$y' \uparrow \quad y'' \uparrow$

$\Rightarrow$ order 2

Why is Taylor Extrapolation rarely used??

Usually only get access to derivatives from final f, not derivatives (H)

Multi-stage methods

(Multiple f eval per Step)

- Heun's meth.

$\Phi = \frac{1}{2} f(t, y) + \frac{1}{2} f(\dots)$

- Mod. point Sch.

$\Phi = f(t + \frac{1}{2}, y + \frac{1}{2} f(t, y))$

a) general partition Sols

Let $k_1 = f(t, y) = \text{Slope} \in y_t$

$k_2 = f(t + \frac{1}{2}h, y + \frac{1}{2}h k_1)$
$= \text{Slope} \in y_{t+h}$

Use $\Phi = \alpha_1 k_1 + \alpha_2 k_2$

i.e. $\mu = \frac{1}{2}, \alpha_2 = 1 \quad (\alpha_1 = \alpha) \Rightarrow$ Mod. Sch

$\mu = 1, \alpha_1 = \frac{1}{2} \Rightarrow$ Heun

Now the goal is... what needs to be true for $O(h^2)$ / order 2 method?

Lots of Algebra

$\alpha_1 + \alpha_2 = 1$

$\alpha_2 \mu = \frac{1}{2}$

RUNGE-KUTTA SCHEMES

The most general scheme are the RK (Runge-Kutta) integrators. These take the previous idea to a general setting.

$$\Phi(t, y; h) = \sum_{i=1}^{s} b_i \mathbf{k}_i$$

$$\mathbf{k}_1 = f(t, y)$$

$$\mathbf{k}_i = f(t + a_i, y + h\sum_{j=1}^{i-1} b_j \mathbf{k}_j).$$

Here, we have $a_i = \sum_{j=1}^{i-1} b_j$ and $\sum_i a_i = 1$.

Ends k_5

Uses $k_1 \ldots k_5$ to get 4th order Err?

$\sum_{ij}$ Combo of prev. terms used in prev. proj.

Use $k_1 \ldots k_5$ to get order 5 for $k_1 \ldots k_4$

For instance, the classic formula in order 4 with:

$$\Phi(t, \mathbf{y}; h) = \frac{h}{6}(\mathbf{k}_1 + 2\mathbf{k}_2 + 2\mathbf{k}_3 + \mathbf{k}_4)$$

$\mathbf{k}_1 = f(t, \mathbf{y})$ Gives k_2

$\mathbf{k}_2 = f(t + h/2, \mathbf{y} + h/2\mathbf{k}_1)$

$\mathbf{k}_3 = f(t + h/2, \mathbf{y} + h/2\mathbf{k}_2)$

$\mathbf{k}_4 = f(t + h, \mathbf{y} + h\mathbf{k}_3)$

SOFTWARE

Matlab's ODE suite implements:[4]

1. ode45: 4th-order method (best general choice)

5

2. ode23: 2nd-order method
3. ode23t: 2nd-order method tuned for stiff problem using a Iacobian.
4. ode23tb: 1st-order method tuned for stiff problem

Use ode23 or ode23t for stiff problems

This was designed by Shampine and Reichelt.[5]

Julia has a suite of ODE solvers that's based on the same ideas as Matlab in the ODE package.[3] The methods are the same as Matlab.

SciPy has many of the same methods implemented.[4]
