

Lecture 7

HW 2 posted soon.

Why is
 $\max_{x \neq 0} \frac{f(Ax)}{f(x)} = \frac{f(Bx)}{f(x)}$
 $\leq \max_{x,y} \frac{f(Ax)}{f(x)} + \frac{f(Ay)}{f(y)}$

Even if $A \neq 0$, will
 $x_{k+1} = (I - \alpha A)x_k + \alpha \underline{b}$ $\parallel$
 Will converge to $x^* = A^{-1}\underline{b}$?
 $\parallel 1 - \alpha \lambda \parallel < 1$ No, eigenvalue
 If show this yes, I think it's too
 understood correct.

How do we pick α in Richardson?
 Why are $\parallel AB \parallel_{\text{max}} \leq \parallel A \parallel_{\text{max}} \cdot \parallel B \parallel_{\text{max}}$
 and $\parallel A x \parallel_{\text{vec}} \leq \parallel A \parallel_{\text{max}} \parallel x \parallel_{\text{vec}}$
 Both submultiplicative?
 Do we need to read & write Julia on the exam?
 Will this class help us find an AI related job?
 Why do we change the algorithm when solving diff. systems?

Which is more parallel friendly? CSC or CSR?
 How are sparse graph coloring across a machine?
 How to choose step in gradient descent automatically?
 How do we check convexity?
 Typo: $\det(A) \neq 0$ but $\det(A) = 1$

Solve non-convex via gradient descent?
 Time complexity for $Ax = \underline{b}$?
 If $Ax = \underline{b}$ has infinite soln, can we use iterative methods to find one?

Submult. property is "weird"
 $f_n(x) = \parallel x \parallel$ when x is in $\mathbb{R}^2$
 $f_m(x) = \parallel x \parallel$ when x is in $\mathbb{R}^m$
 $f_{\max}(AB) \leq f_{\max}(A) \cdot f_{\max}(B)$

$x_{i-2} = 0$
 for $i = 1:n$
 $x_{i-2} += x[i] * x[i]$
 What does this compute?

Which is more parallel friendly?
 CBR? CSC?

How to pick α in Richardson?
 if $A \succ 0$, then $\alpha = \frac{2}{\lambda_1 + \lambda_n}$
 (± shift). $\lambda_1 + \lambda_n$ Extremal Eigenvals.

$\lambda_1 \geq 0$
 $\lambda_n \leq \parallel A \parallel$ for any norm.
 Use $\alpha = \frac{2}{\min(\parallel A \parallel_{\infty}, \parallel A \parallel_1)}$ as a first guess.

$f(x) = \frac{1}{2} x^T A x - x^T \underline{b}$
 $\min f(x) \Leftrightarrow Ax = \underline{b}$
 When A is sym. pos. def.

At each step of Richards
 $\underline{x}_{k+1} = \underline{x}_k + \alpha \underline{r}_k$
 1 Variable function in α .
 $f(\alpha) = \frac{1}{2} (\underline{x}_k + \alpha \underline{r}_k)^T A (\underline{x}_k + \alpha \underline{r}_k) - (\underline{x}_k + \alpha \underline{r}_k)^T \underline{b}$

$f'(x) = 0$
 $f(x) = a x^2 + b x + c$

$A \succ 0, A = A^T$
 $f(x) = \frac{1}{2} x^T A x - x^T \underline{b}$
 has a unique soln!
 $H(x) = A$

If $A \geq 0, A = A^T$
 Then we have and $A \neq 0$, then
 There exists $\underline{z}$ st.
 $A \underline{z} = 0$. ($\underline{z} \neq 0$)
 $A \underline{x} = \underline{b}$
 $A(x + \underline{z}) = A \underline{x} + A \underline{z} = \underline{b} + \underline{0}$

$\min \frac{1}{2} x^T A x - x^T \underline{b}$
 st. $\parallel x \parallel$ is as small as possible.
 MINRES[©] will solve this!
 (one little trick).
 $x^* = A^+ \underline{b}$
 pseudo-inverse has this property!

$\min f(\alpha)$
 α

$f(x) = \frac{1}{2} x^T A x - x^T \underline{b}$
 $\min f(x) \Leftrightarrow Ax = \underline{b}$
 When A is sym. pos. def.

At each step of Richards
 $\underline{x}_{k+1} = \underline{x}_k + \alpha \underline{r}_k$
 1 Variable function in α .
 $f(\alpha) = \frac{1}{2} (\underline{x}_k + \alpha \underline{r}_k)^T A (\underline{x}_k + \alpha \underline{r}_k) - (\underline{x}_k + \alpha \underline{r}_k)^T \underline{b}$

$f'(x) = 0$
 $f(x) = a x^2 + b x + c$
