Edited by: Ernesto Estrada

[Received on 21 July 2019; editorial decision on 9 September 2019; accepted on 3 October 2019]
Preferential attachment (PA) models are a common class of graph models which have been used to explain why power-law distributions appear in the degree sequences of real network data. Among other properties of real-world networks, they commonly have non-trivial clustering coefficients due to an abundance of triangles as well as power laws in the eigenvalue spectra. Although there are triangle PA models and eigenvalue power laws in specific PA constructions, there are no results that existing constructions have both. In this article, we present a specific Triangle Generalized Preferential Attachment Model that, by construction, has non-trivial clustering. We further prove that this model has a power law in both the degree distribution and eigenvalue spectra.

Keywords: power law; preferential attachment; spectra.

## 1. Introduction

The idea of preferential attachment ( PA ) has a lengthy history in explaining 'rich-get-richer' models [1, 2]. In the context of networks, a PA model suggests that when agents join a network, they form links to existing nodes with large degrees. These models offer a simple local rule that helps explain the presence of highly skewed or power-law degree distributions in real-world networks [3]. While a simple and compelling mathematical model, there are weaknesses in the relationship between PA models and real-world data. One of the most striking is the lack of clustering in PA network models. Consequently, there has been a line of work on generalized PA models that include ways to address the lack of clustering. First, Holme and Kim [4] proposed a triangle PA model, where agents arrive and link to a node based on its degree and also link to a neighbour of that node to form a triangle. Later, Ostroumova et al. [5] generalized a family of PA models and showed that they had power-law degree distributions and in some cases high clustering. We note that clustering coefficients and degree distributions reflect intrinsically different properties as there are networks such as a barbell graph (extremely high clustering) and a bipartite network (no clustering) which both have the same degree distribution, but radically different clustering coefficients, this has also been observed in graph models [6].

Our work follows in this vein, and in this article, we analyse a specific set of PA networks. The specific Triangle Generalized Preferential Attachment (TGPA) model will be introduced formally in Section 3. Informally, the networks grow by inserting two edges that form an idealized triangle (with an already existing 3rd edge) at each step, where the endpoints are chosen via PA. Our novel analysis of the model shows that it will produce networks with power-law degree distributions (Theorem 6.1, Corollary 7.2), and power-law spectral distributions (Theorem 6.2). In our design and analysis of TGPA, we also proved that the models presented by Avin et al. [7] and the Holme-Kim model [4] have power laws in the spectra as well. The result on the Holme-Kim model we get for free from our proof of the power law on TGPA. We prove the result on the Avin et al. model separately, in a similar method as in TGPA.

Our interest in the TGPA model stems from our recent finding on the reliable presence of power laws in the eigenvalue spectrum of the adjacency matrix [8]. Specifically, in [8], we found that realworld networks of a variety of types were more likely to have a statistically significant power law in the eigenvalues of the adjacency matrix than in the degree distribution. The focus on the existence of power laws in graph models has been primarily focused on the degree distribution in the past. While standard PA models have been shown to have power laws in the eigenvalue spectra [ 9,10 ], this model does not have significant clustering coefficients as already mentioned.

For a few decades, power laws, or highly skewed degree distributions, were commonly accepted properties of real-world networks. As the diversity of data studied continues to grow, alternative distributions that provide superior characterizations of degree distributions of real-world networks have emerged [11, 12]. Our point with this article is not the power law results necessarily, but rather the study of simple models for networks, and an understanding of what contributes to properties of these networks reminiscent of real-world data. That is, our goal is to understand driving factors underlying simple generative mechanisms for networks and to characterize the emergent properties of those models.

In summary, the primary contributions of this manuscript are:

1. We present the TGPA model: A model which imposes higher-order structure directly into the network (Section 3).
2. We show that TGPA produces graphs with significant clustering (Section 4).
3. We extend the results presented on the Generalized Preferential Attachment (GPA) model (in [7]), to show the eigenvalues follow a power-law distribution (Section 5).
4. We conduct extensive analysis of TGPA to show that the degrees follow a power-law distribution with an exponent which can range between $(1, \infty)$ (Section 7), and that the eigenvalues follow a power-law distribution (Section 6).
5. We extend the results presented on the model presented by Holme and Kim [4] to show the eigenvalues follow a power-law distribution (Section 6.1).

In our experience establishing these results, one technical challenge involved the ideas in Lemma 6.2, where the existing approach fundamentally assumed that edges were not added in small groups. The code to reproduce our experiments is available online at https://github.com/eikmeier/TGPA.

## 2. Preliminaries and related work

Denote a graph $G$ by its set of vertices $V$ and edges $E$. A graph with $n$ vertices can be represented as an $n \times n$ adjacency matrix $\boldsymbol{A}$, where $\boldsymbol{A}_{i j}=1$ if edge ( $i, j$ ) is in the graph, and $\boldsymbol{A}_{i j}=0$ otherwise. The

Table 1 Notation in our article

| $G_{t}=\left(V_{t}, E_{t}\right)$ | A graph at time step $t$ with vertices $V$ and edges $E$ |
| :--- | :--- |
| $\boldsymbol{A}$ | The adjacency matrix |
| $d_{t}(v)$ | The degree of vertex $v$ at time $t$ |
| $e_{t}$ | The number of edges at time $t$ |
| $m_{k, t}$ | The number of nodes at time $t$ with degree $k$ |

degree of vertex $i$ is the number of vertices $j$ such that $\boldsymbol{A}_{i j}=1$. In this manuscript, we will be primarily concerned with undirected, simple, graphs, meaning $\boldsymbol{A}_{i j}=\boldsymbol{A}_{j i}$ for all $i, j$, and $\boldsymbol{A}_{i i}=0$ for all $i$.

We will be concerned with graph models that evolve over time. There are a huge diversity of graph generation schemes, many of which have been analysed in theory and in practice. For example, latent space graphs [13] and GPA [14]. Define a non-empty initial graph $G_{0}$ with vertices, $V_{0}$, and edges, $E_{0}$. At each time step $t=1,2, \ldots$ perform some action on $G_{t-1}$ (such as adding new vertices or edges) to obtain $G_{t}=\left(V_{t}, E_{t}\right)$. Continue until the graph is sufficiently large. Denote the degree of vertex $v$ at time $t$ to be $d_{t}(v)$. Let $e_{t}$ denotes the number of edges at time $t$, and let $m_{k, t}$ be the number of nodes at time $t$ with degree $k$.

### 2.1 Preferential attachment

PA describes a mechanism of graph evolution in which nodes with higher degree tend to continue gaining neighbours. When a new node $u$ is added to the graph at time $t$, choose another existing vertex $v$ with probability proportional to its degree. Formally, choose vertex $v$ with probability

$$
\begin{equation*}
\gamma_{t}(v)=\frac{d_{t-1}(v)}{\sum_{w \in V_{t-1}} d_{t-1}(w)} . \tag{2.1}
\end{equation*}
$$

Then add an edge connecting $u$ to $v$. PA is meant to model the power-law behaviour that is often seen in real-world networks [15-17], that is a few vertices tend to have very large degree while most vertices have fairly low degree. A set of values $x_{1}, x_{2}, \ldots x_{k}$ satisfies a power law if it is drawn from a probability distribution $p(x) \propto x^{-\beta}$ for some $\beta$.

The PA graph model is found in a few different forms. In the model by Barabási and Albert [3], often called the BA model, at every new time step a new vertex is formed with $m$ edges. Each of the edges is then connected to an existing node chosen using PA, that is based on their degrees.

In a slight variation found in [18, 19], at each time step $t$, a new node is added with probability $p$. Along with the new node is an edge between the new node and an existing node picked via PA. With probability $1-p$ a new edge is added between two existing nodes, both chosen via PA. These two models generate slightly different distributions, but fundamentally give very similar graphs. We present our model TGPA in two forms matching these differences (Section 3).

In Sections 2.2 and 2.3, we discuss a few variations of the PA model. There exist other variations of PA [5, 20-22] which we will not detail here.

### 2.2 Generalized preferential attachment

The GPA model was defined by Avin et al. [7]. In this model, in addition to adding new vertices and edges, there is also an option in each time step of adding a new component. Furthermore, the parameters may change over time, if desired. Start with an arbitrary initial non-empty graph $G_{0}$. For time $t \geq 1$, the graph $G_{t}$ is constructed by performing either a node event with probability $p_{t} \in[0,1]$, an edge event with probability $r_{t} \in\left[0,1-p_{t}\right]$, or a component event with probability $q_{t}=1-p_{t}-r_{t}$. In a node event, a new vertex $v$ is added to the graph, along with an edge $(u, v)$ where $u$ is chosen from $G_{t-1}$ with probability $\gamma_{t}(u)$. In an edge event, a single new edge $(u, w)$ is added, with $u$ and $w$ both nodes in $G_{t-1}$. The edge endpoint $u$ is chosen with probability $\gamma_{t}(u)$ and the endpoint $w$ is chosen with probability $\gamma_{t}(w)$, so the edge itself is chosen with probability $\gamma_{t}(u) \cdot \gamma_{t}(w)$, which gives a full probability distribution over edges (recall that multiedges and self-loops are allowed). And in a component event, two new nodes $v_{1}, v_{2}$ are added along with edge ( $v_{1}, v_{2}$ ). Exactly one edge is added at each time step, so the number of edges in $G_{t}$ is equal to $e_{0}+t$.

The key difference in GPA over the PA model discussed in Section 2.1 is the ability to add new components to the graph. In [7], it is proved that the degree distribution follows a power law. In this manuscript, we further prove that the eigenvalues follow a power-law distribution (see Section 5).

We will also work with a slight variation of the GPA model, along the lines of the alternate version of the PA model defined in $[3,9]$ and discussed in Section 2.1. Start with an empty graph. Note: this model need not start as an empty graph, we just follow the convention of [3, 9]. Since all of our analysis is in asymptotics, it should have no impact. At time $t=1,2, \ldots$ do one of the following: with probability $p$ add a new vertex $v_{t}$ and an edge from $v_{t}$ to some other vertex in $u$ where $u$ is chosen with probability

$$
\operatorname{Pr}\left[u=v_{i}\right]= \begin{cases}\frac{d_{t}\left(v_{i}\right)}{2 t_{i}-1}, & \text { if } v_{i} \neq v_{t}  \tag{2.2}\\ \frac{1}{2 t-1}, & \text { if } v_{i}=v_{t}\end{cases}
$$

and with probability $1-p$ add two new vertices and an edge between them. For some constant $m$, every $m$ steps contract the most recent $m$ vertices added through the PA step to form a super vertex. Notice that Equation (2.2) is not quite the same as $\gamma_{t}$ in Equation (2.1). Equation (2.2) allows for nodes to be added with self-loops. In both versions, loops are allowed in the edge step. Regardless, the allowance of self-loops has little effect as the graph becomes large, and we remove all self-loops in our final graph for experimental analysis.

### 2.3 Triad formation

Holme and Kim [4] introduced a Triad Formation step into the BA version of the PA model (see Section 2.1). After each PA step in which a new vertex $v$ is added and some edge is added ( $v, u$ ), a triangle is closed with probability $p_{t}$ by choosing a neighbour of $u, u_{2}$, and adding edge ( $v, u_{2}$ ). An example network is shown in Figure 1 under 'Holme'. The average number of triad closures per added vertex is $m_{t}=(m-1) p_{t}$. It is shown in [4] that the network follows a power law in the degrees with an exponent of 3 and has clustering coefficients which can be tuned by the parameter $m_{t}$. Our model incorporates something very similar to this triad formation, but with less regular structure due to an added component step, and with a larger range of possible power-law exponents. See Section 3 for the description of our model, and Lemma 7.2 for the result on the range of degree power-law exponents.

### 2.4 Higher-order features in graphs

Recently, there has been interest in analysing the higher-order features in graphs [23-28]. One of the earlier motivations for this direction is the famous paper by Milo et al. [29] on the presence of motifs in real-world networks. Likewise, there are new models which aim to match these higher-order features. For example, the triad formation model described in Section 2.3 [4], and the family of PA models [5] discussed in Section 1. Another model, HyperKron, places a distribution over hyperedges and inserts motifs instead of edges [30] and is specifically shown to have higher-order clustering. The study of higher-order features is growing and complex, it is also studied in multi-layer networks, temporal data, and components of graphs. See [31] for a nice overview of work in higher-order network analysis.

## 3. TGPA

In this section, we present our model which we call TGPA. This model is motivated by the purpose of adding higher-order structure into the resulting graph as discussed in Section 2.4, and a recent paper [7] which shows a model of PA with any power-law exponent (Section 2.2). We present two different versions of the model. The first, in Section 3.1 follows the PA model as described by [3, 9], and the second in Section 3.2 follows the PA model as described in [7,18]. Though these models are not the same, they share similar properties. In Sections 6 and 7, we will see each formulation is useful for the analysis of the models. Figure 1 shows some example graphs generated by TGPA compared to existing models.

## 3.1 $\operatorname{TGPA}(p, q)$

Start with an empty graph. At time $t=1,2, \ldots$ do one of the following:

1. (node event) With probability $p$, add a new vertex $v_{t}$, and an edge from $v_{t}$ to some other vertex $u$ where $u$ is chosen with probability

$$
\operatorname{Pr}\left[u=v_{i}\right]=\left\{\begin{array}{ll}
\frac{d_{t}\left(v_{i}\right)}{t-2}, & \text { if } v_{i} \neq v_{t}  \tag{3.1}\\
\frac{2}{4 t-2}, & \text { if } v_{i}=v_{t}
\end{array} .\right.
$$

Then pick a neighbour of $u$, call it $w$, and also add an edge from $v_{t}$ to $w$. We pick $w$ with probability

$$
\operatorname{Pr}\left[w=v_{i}\right]=\left\{\begin{array}{ll}
\frac{\# \text { edges between } u, w}{d_{t}-1(u)}, & \text { if } v_{i} \neq u  \tag{3.2}\\
\frac{2 . \# \text { self-lop of } u}{d_{t-1}(u)}, & \text { if } v_{i}=u
\end{array} .\right.
$$

2. (component event) With probability $q=1-p$ add a wedge to the graph ( 3 new nodes with 2 edges).
3. For some constant $m$, every $m$ steps contract the most recently added vertices through the PA steps (in step 1) to form a super vertex.

Note that vertex $w$ (chosen in step 1) is also chosen via PA. The probability of picking $w$ is the probability of picking $u$ as a neighbour of $w$ times the probability of picking $w$ :

$$
\operatorname{Pr}\left[w=v_{i}\right]=\frac{\sum_{u \in N(w)} d_{t-1}(u)}{4 t-2} \cdot \frac{\text { num edges between } u, w}{d_{t-1}(u)}=\frac{d_{t}(w)}{4 t-2} .
$$

Fig. 1. Examples of 50 node graphs. The top two figures were generated using $p=0.8, r=0.1, q=0.1$. The graphs on the bottom were generated using $m=2$, and $\operatorname{TGPA}(p, q)$ used $p=0.85$. See the text for the details on these parameters.

### 3.2 TGPA $\left(p_{t}, r_{t}, q_{t}\right)$

Start with a graph with $e_{0}$ edges. At time $t=1,2, \ldots$ do one of the following:

1. (Node event) With probability $p_{t}$, add a new vertex $v_{t}$, and an edge from $v_{t}$ to some other vertex $u$ where $u$ is chosen with probability given in Equation (3.1). Then pick a neighbour of $u$, call it $w$, as in Equation (3.2). Add edge an edge from $v_{t}$ to $w$.
2. (Wedge event) With probability $r_{t}$ add a wedge to the graph by picking two nodes using PA: $v_{1}, v_{2}$. Pick the third node uniformly from a neighbour of $v_{1}$, call it $w$. Add edges $\left(v_{1}, v_{2}\right)$ and $\left(v_{1}, w\right)$.
3. (Component event) With probability $q_{t}$ add a wedge to the graph ( 3 new nodes with 2 edges).

TABLE 2 Clustering coefficients for three real-world networks, and generated models. TGPA is able to generate data with much larger clustering coefficients, compared to GPA

| Network name | Edges | Global clust | Local clust | HO global | HO local |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Auburn (18k vertices) | 974 k | 0.137 | 0.223 | 0.107 | 0.172 |
| TGPA(18k, $0.987,10,150):$ | 640 k | 0.25 | 0.22 | 0.118 | 0.03 |
| GPA(18k,0.001,0.999,2): | 906 k | 0.021 | 0.030 | 0.005 | 0.014 |
| Berkeley (13k vertices) | 852 k | 0.114 | 0.207 | 0.0876 | 0.156 |
| TGPA(13k,0.99, 10, 58) | 502 k | 0.104 | 0.185 | 0.034 | 0.025 |
| GPA(13k,0.001,0.999,2) | 502 k | 0.024 | 0.034 | 0.005 | 0.015 |
| Princeton (7k vertices) | 293 k | 0.237 | 0.164 | 0.091 | 0.146 |
| TGPA(7k,0.987,10,100): | 207 k | 0.298 | 0.251 | 0.148 | 0.053 |
| GPA(7k,0.001,0.999,2): | 255 k | 0.038 | 0.054 | 0.009 | 0.025 |

## 4. Significant clustering coefficients

We analysed three networks from the Facebook 100 dataset [32], each of which is a set of users at a particular university. We computed the global clustering coefficient: $6\left|K_{3}\right| /|W|$, where $\left|K_{3}\right|$ is the number of triangles and $|W|$ is the number of wedges, and average local clustering coefficient: the average of $2\left|K_{3}(u)\right| /|W(u)|$ for all nodes $u$, where $K_{3}(u)$ denotes triangles for which $u$ is a member. We also considered higher-order clustering coefficients, defined in [28] to be the fraction of appropriate motifs which are closed into 4-cliques.

To fit the TGPA $(p, q)$ model (Section 3.1) to the real-world networks, we noted that the average degree of our model, the total degrees divided by the number of nodes, is approximately $(2 m(1-p)+$ $2 m) /(m(1-p)+1)$. Choosing the average degree gives a relationship between parameters $m$ and $p$. We tested various sets of parameters to obtain the best possible fit. We started both TGPA and GPA with a $k$-node clique. Table 2 lists the parameters we chose for the TGPA model as TGPA $(n, p, k, m)$, which produces an $n$ node graph starting from a $k$ node clique. For comparison, we also fit the GPA model (Section 2.2). The parameters in Table 2 are GPA $(n, p, r, k)$. Notice that TGPA maintains much more significant clustering coefficients across all measures.

## 5. Eigenvalue power law in GPA

In this section, we present results for the GPA model presented in [7] and discussed in Section 2.2, relating to the distribution of the eigenvalues of a graph formed in the model. Note that in order to get our desired result (Theorem 5.2), we also prove that the degree distribution has a power-law distribution (Theorem 5.1). This was already proven in [7], but the version of our proof is useful in order to obtain Theorem 5.2. The results and proofs mirror those in [9], but provide a useful step towards the results on the TGPA model in Section 6. All proofs are included in Appendix A.

Fix parameter $p$. Denote $G_{t}^{m}$ as the GPA Graph at time $t$ with contractions of size $m$.

Lemma 5.1 Let $d_{t}(s)$ be the degree of vertex $s$ in $G_{t}^{m}$, for any time $t$ after $s$ has been added to the graph. Let $a^{(k)}=a(a+1)(a+2) \cdots(a+k-1)$ be the rising factorial function. Let $s^{\prime}$ be the time at which
node $s$ arrives in the graph. Then for any positive integer $k$,

$$
\mathbb{E}\left[\left(d_{t}(s)\right)^{(k)}\right] \leq(2 m)^{(k)} 2^{p k / 2}\left(\frac{t}{s^{\prime}}\right)^{p k / 2}
$$

Now define a supernode to be a collection of nodes viewed as one. The degree of a supernode is the sum of the degrees of the vertices in the supernode.

Lemma 5.2 Let $S=\left(S_{1}, S_{2}, \ldots, S_{l}\right)$ be a disjoint collection of supernodes at time $t_{0}$. Assume that the degree of $S_{i}$ at time $t_{0}$ is $d_{t_{0}}\left(S_{i}\right)=d_{i}$. Let $t$ be a time later than $t_{0}$. Let $p_{S}\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right)$ be the probability that each supernode $S_{i}$ has degree $r_{i}+d_{i}$ at time $t$. Let $d=\sum_{i=1}^{l} d_{i}, r=\sum_{i=1}^{l} r_{i}$. If $d=o\left(t^{1 / 2}\right)$ and $r=o\left(t^{2 / 3}\right)$, then

$$
p_{S}\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right) \leq\left(\prod_{i=1}^{l}\binom{r_{i}+d_{i}-1}{d_{i}-1}\right)\left(\frac{t_{0}+1}{t}\right)^{p d / 2} \exp \left\{2+t_{0}-\frac{p d}{2}+\frac{3 p r}{t^{p / 2}}\right\} .
$$

Theorem 5.1 Let $m, k$ be fixed positive integers, and let $f(t)$ be a function with $f(t) \rightarrow \infty$ as $t \rightarrow \infty$. Let $\Delta_{1} \geq \Delta_{2} \geq \ldots \geq \Delta_{k}$ denote the degrees of the $k$ highest degree vertices of $G_{t}^{m}$. Then

$$
\frac{t^{p / 2}}{f(t)} \leq \Delta_{1} \leq t^{p / 2} f(t) \text { and } \frac{t^{p / 2}}{f(t)} \leq \Delta_{i} \leq \Delta_{i-1}-t^{p / 2} f(t)
$$

for $i=1,2, \ldots, k w h$.
The factor of $t^{p / 2}$ in Theorem 5.1 implies a power-law distribution in the largest degrees with exponent $\beta=(2+p) / p$. This can be seen by using a martingale argument, as described in [33] for instance. Notice that depending on the value chosen for $p$, we can obtain a power law fit with exponents ranging between 3 and $\infty$.

The next result relates maximum eigenvalues and maximal degrees in the GPA model. It is similar to results found in $[9,10,34,35]$. It says that if the degrees follow a power law with exponent $\beta$, then the spectra follows a power law as well, with exponent $2 \beta-1$.

Theorem 5.2 Let $k$ be a fixed integer, and let $f(t)$ be a function with $f(t) \rightarrow \infty$ as $t \rightarrow \infty$. Let $\lambda_{1} \geq \lambda_{2} \geq \ldots \geq \lambda_{k}$ be the $k$ largest eigenvalues of the adjacency matrix of $G_{t}^{m}$. The for $i=1, \ldots, k$, we have $\lambda_{i}=(1+o(1)) \Delta_{i}^{1 / 2}$, where $\Delta_{i}$ is the $i$ th largest degree.

## 6. Analysis of TGPA $(p, q)$

In this section, we present results on the degrees and spectra of the TGPA $(p, q)$ model, which was defined in Section 3.1. The proofs follow the proof techniques presented in Section 5. The key difference in these proofs is the fact that two edges may be added in each time step. This makes the PA much more tedious to track through graph generation. In Lemma 6.2 for example, we consider disjoint (but not disconnected) sets of supernodes; the probability of the supernodes increasing in degree is not independent from one other. The full proofs are in Appendix B.

Fix parameter $p$. Denote $G_{t}^{m}(p, q)$ as the TGPA Graph at time $t$ with contractions of size $m$.

Lemma 6.1 Let $d_{t}(s)$ be the degree of vertex $s$ in $G_{t}^{m}(p, q)$, for any time $t$ after $s$ has been added to the graph. Let $a^{(\bar{k})}=a(a+2)(a+4) \cdots(a+k-2)$ be a modified rising factorial function. Let $s^{\prime}$ be the time at which node $s$ arrives in the graph. Then for any positive integer $k$,

$$
\mathbb{E}\left[\left(d_{t}(s)\right)^{(\bar{k})}\right] \leq(4 m)^{(\bar{k})} 2^{p k}\left(\frac{t}{s^{\prime}}\right)^{p k}
$$

Lemma 6.2 Let $S=\left(S_{1}, S_{2}, \ldots, S_{l}\right)$ be a disjoint collection of supernodes at time $t_{0}$. Assume that the degree of $S_{i}$ at time $t_{0}$ is $d_{t_{0}}\left(S_{i}\right)=d_{i}$. Let $t$ be a time later than $t_{0}$. Let $p_{S}\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right)$ be the probability that each supernode $S_{i}$ has degree $r_{i}+d_{i}$ at time $t$. Let $d=\sum_{i=1}^{l} d_{i}, r=\sum_{i=1}^{l} r_{i}$. If $d=o\left(t^{1 / 2}\right)$ and $r=o\left(t^{2 / 3}\right)$, then

$$
p_{S}\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right) \leq\left(\prod_{i=1}^{l}\binom{r_{i}+d_{i}-1}{d_{i}-1}\right)\left(\frac{t_{0}}{t-1}\right)^{p d} \exp \left\{3+2 t_{0}-p d+\frac{19 p r}{4 t^{p}}\right\} .
$$

Theorem 6.1 Let $m, k$ be fixed positive integers, and let $f(t)$ be a function with $f(t) \rightarrow \infty$ as $t \rightarrow \infty$. Let $\Delta_{1} \geq \Delta_{2} \geq \ldots \geq \Delta_{k}$ denote the degrees of the $k$ highest degree vertices of $G_{t}^{m}(p, q)$. Then,

$$
\frac{t^{p}}{f(t)} \leq \Delta_{1} \leq t^{p} f(t) \text { and } \frac{t^{p}}{f(t)} \leq \Delta_{i} \leq \Delta_{i-1}-t^{p} f(t)
$$

for $i=1,2, \ldots, k w h$.

The factor of $t^{p}$ in Theorem 6.1 implies a power-law distribution with exponent $\alpha=(1+p) / p$. This can be seen by using a martingale argument, which has been done a number of times. See for instance [33]. Notice that depending on the value chosen for $p$, we can obtain a power law fit with exponents ranging between 2 and $\infty$.

Theorem 6.2 Let $k$ be a fixed integer, and let $f(t)$ be a function with $f(t) \rightarrow \infty$ as $t \rightarrow \infty$. Let $\lambda_{1} \geq \lambda_{2} \geq \ldots \geq \lambda_{k}$ be the $k$ largest eigenvalues of the adjacency matrix of $G_{t}^{m}(p, q)$. The for $i=1, \ldots, k$, we have $\lambda_{i}=(1+o(1)) \Delta_{i}^{1 / 2}$, where $\Delta_{i}$ is the $i$ th largest degree.

In the analysis of this proof, we restrict $p$ to be greater than 9/32. This comes in Claim B.7, and constrains the exponent in the power law to be between 2 and 5 . For the proof, we will show that with high probability $G$ contains a star forest $F$, with stars of degree asymptotic to the maximum degree vertices of $G$. Then we show that $G \backslash F$ has small eigenvalues. Finally, we can use Rayleigh's principle to say that the large eigenvalues of $G$ cannot be too different than the large eigenvalues of $F$. See Appendix B for the full proof.

### 6.1 Spectral power law in Holme-Kim model

The model which we have defined as TGPA(p,q) is equivalent to the model defined by Holme and Kim [4] with $q=0$. We note here that then we get for free that the model by Holme and Kim also has a power law in the spectrum, by using the same analysis with $q=0$ and $p=1$.

## 7. Analysis of TGPA $\left(p_{t}, r_{t}, q_{t}\right)$

Consider $\operatorname{TGPA}\left(p_{t}, r_{t}, q_{t}\right)$, which was described in Section 3.2. The parameters $p_{t}, r_{t}, q_{t}$ can change over time, though we will restrict the ways in which the parameters can evolve in Section 7.2.

### 7.1 Recursive relation for $m_{k, t}$

Recall that $m_{k, t}$ is the number of nodes at time $t$ with degree $k$. We wish to write down a relationship for $m_{k, t+1}$ in terms of $m_{k^{\prime}, t}$ for $k^{\prime} \leq k$. Recall also that the number of edges at time $t$ is $e_{t}=e_{0}+2 t$, and the total sum of degrees at any time $t$ is $2 e_{t}$. Note that for this reason, we need only focus on $m_{k, t}$ for $1 \leq k \leq 2 e_{t}$.

Let $\mathscr{F}_{t}$ denote the $\sigma$-algebra generated by the graphs $G_{0}, G_{1}, \ldots, G_{t}\left(\mathscr{F}_{t}\right.$ holds the history of events up until time $t$ ). We wish to calculate the expected value of $m_{k, t+1}$, conditioned on the previous time steps, held in $\mathscr{F}_{t}$. Fix $k \geq 2$. Since $0 \leq d_{t+1}(v)-d_{t}(v) \leq 4$ for every node $v$ and time $t$, we have

$$
\begin{equation*}
\mathbb{E}\left[m_{k, t+1} \mid \mathscr{F}\right]=\sum_{\left\{v: k-4 \leq d_{t}(v) \leq k\right\}} \mathbb{P}\left[d_{t+1}(v)=k\right] . \tag{7.1}
\end{equation*}
$$

Recall $\gamma_{t}(v)$ from Equation (2.1). Denote $\theta_{t}(v)$ as 2 times the number of self-loops in which $v$ is involved divided by $\sum_{w \in V_{t-1}} d_{t-1}(w)$. (i.e. the proportion of edges which are self-loops on $v$ ). If $d_{t+1}(v)=4$, then there are at most 5 possible values for $d_{t}(v)$ when $k \geq 4$ :
(i) $d_{t}(v)=k$. In this case, there must have either been a node event not involving $v$ (this occurs with probability $p_{t+1}\left(1-2 \gamma_{t+1}(v)+\theta_{t+1}(v)\right)$ ), or a wedge event not involving $v$ (with probability $\left.r_{t+1}\left(1-\gamma_{t+1}(v)\right)\left(1-2 \gamma_{t+1}(v)+\theta_{t+1}(v)\right)\right)$, or a component event (with probability $\left.q_{r+1}\right)$.
(ii) $d_{t}(v)=k-1$. In this case, there must have either been a node event where $v$ is involved as the first node (probability $p_{t+1} \cdot \gamma_{t+1}(v) \cdot\left(1-\theta_{t+1}(v)\right)$ ), or where $v$ is involved as the second node (probability $p_{t+1}\left(\gamma_{t+1}(v)-\theta_{t+1}(v)\right)$ ), or a wedge event in which $v$ is involved as the first node (with probability $r_{t+1}\left(\gamma_{t+1}(v)-\gamma_{t+1}(v)^{2}-\theta_{t+1}(v)+\gamma_{t+1}(v) \cdot \theta_{t+1}(v)\right)$ ) or as the third node (probability $\left.r_{t+1}\left(1-\gamma_{t+1}(v)\right)\left(\gamma_{t+1}(v)-\theta_{t+1}(v)\right)\right)$.
(iii) $d_{t}(v)=k-2$. In this case, there must have either been a node event in which $v$ is picked as both nodes involved (with probability $p_{t+1} \cdot \theta_{t+1}(v)$ ) or there must have been a wedge event in which $v$ is involved as the second node (with probability $r_{t+1} \cdot \theta_{t+1}(v)\left(1-\gamma_{t+1}(v)\right)$ ) or as the first and third nodes (with probability $r_{t+1} \cdot \gamma_{t+1}(v)\left(1-\gamma_{t+1}(v)+\theta_{t+1}(v)\right)$ ).
(iv) $d_{t}(v)=k-3$. In this case, there must have been a wedge event where $v$ was involved as the first and second nodes or there was a wedge event where $v$ was involved as the second and third nodes (these events occur in combination with probability $2 r_{t+1} \gamma_{t+1}(v)\left(\gamma_{t+1}(v)-\theta_{t+1}(v)\right)$ ).
(v) $d_{t}(v)=k-4$. In this case, there must have been a wedge event where $v$ is picked for all three wedges, which happens with probability $r_{t+1} \cdot \gamma_{t+1}(v) \cdot \theta_{t+1}(v)$

Let $\alpha_{k, t}=k /\left(2 e_{t}\right)$. Then for every $v$ such that $d_{t}(v)=i, \gamma_{t+1}(v)=\alpha_{i, t}$. In order to ease the exposition, and for short hand, we define values $A, B, C, D, E$ for each of the probabilities calculated above:

$$
\begin{aligned}
& A_{k, t}=p_{t+1, k}\left(1-2 \alpha_{k, t}+\theta_{t+1}(v)\right)+r_{t+1}\left(1-\alpha_{k, t}\right)\left(1-2 \alpha_{k, t}+\theta_{t+1}(v)\right)+q_{t+1}, \\
& B_{k, t}=2 p_{t+1}\left(\alpha_{k, t}-\theta_{t+1}(v)\right)+2 r_{t+1}\left(1-\alpha_{k, t}\right)\left(\alpha_{k, t}-\theta_{t+1}(v)\right),
\end{aligned}
$$

$$
\begin{aligned}
& C_{k, t}=p_{t+1} \theta_{t+1}(v)+r_{t+1}\left(\alpha_{k, t}-\alpha_{k, t}^{2}+\theta_{t+1}(v)\right), \\
& D_{k, t}=2 r_{t+1} \alpha_{k, t}\left(\alpha_{k, t}-\theta_{t+1}(v)\right), \text { and } E_{k, t}=r_{t+1} \alpha_{k, t} \theta_{t+1}(v) .
\end{aligned}
$$

Then $A_{k, t}+B_{k, t}+C_{k, t}+D_{k, t}+E_{k, t}=1$ and $A_{k, t}, B_{k, t}, C_{k, t}, D_{k, t}, E_{k, t} \geq 0$ for every $0 \leq k \leq 2 e_{t}$. Also, by Equation (7.1), for every $k \geq 4$

$$
\begin{equation*}
\mathbb{E}\left[m_{k, t+1} \mid \mathscr{F}\right]=m_{k, t} A_{k, t}+m_{k-1, t} B_{k-1, t}+m_{k-2, t} C_{k-2, t}+m_{k-3, t} D_{k-3, t}+m_{k-4, t} E_{k-4, t} . \tag{7.2}
\end{equation*}
$$

And for remaining values of $k$, we have

$$
\begin{align*}
& \mathbb{E}\left[m_{3, t+1} \mid \mathscr{F}\right]=m_{3, t} A_{3, t}+m_{2, t} B_{2, t}+m_{1, t} C_{1, t} \\
& \mathbb{E}\left[m_{2, t+1} \mid \mathscr{F}\right]=m_{2, t} A_{2, t}+m_{1, t} B_{1, t}+p_{t+1}+q_{t+1} .  \tag{7.3}\\
& \mathbb{E}\left[m_{1, t+1} \mid \mathscr{F}\right]=m_{1, t} A_{1, t}+2 q_{t+1}
\end{align*}
$$

Define

$$
X_{k, t}=\left\{\begin{array}{ll}
m_{k-1, t} B_{k-1, t}+m_{k-2, t} C_{k-2, t}+m_{k-3, t} D_{k-3, t}+m_{k-4, t} E_{k-4, t} & k \geq 4  \tag{7.4}\\
m_{2, t} B_{2, t}+m_{1, t} C_{1, t} & k=3 \\
m_{1, t} B_{1, t}+p_{t+1}+q_{t+1} & k=2 \\
2 q_{t+1} & k=1
\end{array} .\right.
$$

Then, Equations (7.2) and (7.3) can be re-written as

$$
\begin{equation*}
\mathbb{E}\left[m_{k, t+1}\right]=\mathbb{E}\left[m_{k, t}\right] \cdot A_{k, t}+\mathbb{E}\left[X_{k, t}\right] \tag{7.5}
\end{equation*}
$$

### 7.2 Degree power law in TGPA

The following lemma is presented in [7] and is a quick generalization of a result in [18].
Lemma 7.1 ([7]) Suppose that a sequence satisfies the recurrence relation $a_{t+1}=\left(1-b_{t} /\left(t+t_{1}\right)\right) a_{t}+c_{t}$ for $t \geq t_{0}$. Furthermore, let $\left\{s_{t}\right\}$ be a sequence of real numbers with $\lim _{t \rightarrow \infty} s_{t} / s_{t+1}=1, d_{t}=t\left(1-s_{t} / s_{t+1}\right)$, $\lim _{t \rightarrow \infty} b_{t}=b, \lim _{t \rightarrow \infty} c_{t} \cdot t / s_{t}=c, \lim _{t \rightarrow \infty} d_{t}=d$ and $b+d>1$. Then $\lim _{t \rightarrow \infty} a_{t} / s_{t}$ exists and $\lim _{t \rightarrow \infty} a_{t} / s_{t}=c /(b+d)$.

The following theorem and corollary prove that $\operatorname{TGPA}\left(p_{t}, r_{t}, q_{t}\right)$ has a power law in the degree distribution, which we can analyse.

Theorem 7.1 Consider $\operatorname{TGPA}\left(p_{t}, r_{t}, q_{t}\right)$. Let $y_{t}=p_{t}+3 q_{t}$. Assume that $\lim _{t \rightarrow \infty} y_{t}=y<3, \sum_{t=1}^{\infty} y_{t}=\infty$ and $\lim _{t \rightarrow \infty} t \cdot y_{t+1} / \sum_{j=1}^{t} y_{j}=\Gamma>0$. Then letting $\beta=1+2 \Gamma /(3-y)$, the limit $M_{k}=\lim _{t \rightarrow \infty} \mathbb{E}\left[m_{k, t}\right] / \mathbb{E}\left[n_{t}\right]$ exists for every $k \geq 1$ and

$$
\begin{equation*}
M_{k}=\frac{\Gamma}{\Gamma+3 / 2-y / 2} \prod_{j=1}^{k-1} \frac{j}{j+\beta} . \tag{7.6}
\end{equation*}
$$

Proof. This proof will be an induction on $k$. For $k=1$, we use Lemma 7.1 setting $\left(t_{1}, s_{t}, a_{t}, b_{t}, c_{t}\right)=$ $\left(e_{0}, \mathbb{E}\left[n_{t}\right], \mathbb{E}\left[m_{1, t}\right], e_{t}\left(1-A_{1, t}\right), y_{t+1}\right)$. Using Equation (7.5), this gives the limits $b=3 / 2-y / 2$ and $c=d=\Gamma$, which concludes the base case. Now assume the theorem holds for $k-1$, we now prove it for $k$. Again use Lemma 7.1, this time with $\left(t_{1}, s_{t}, a_{t}, b_{t}, c_{t}\right)=\left(e_{0}, \mathbb{E}\left[n_{t}\right], \mathbb{E}\left[m_{k, t}\right], B_{k-1, t} \mathbb{E}\left[m_{k-1, t}\right]+\right.$ $\left.C_{k-1, t} \mathbb{E}\left[m_{k-2, t}\right]+D_{k-3, t} \mathbb{E}\left[m_{k-3, t}\right]+E_{k-4, t} \mathbb{E}\left[m_{k-4, t}\right]\right)$. Then we get $d=\Gamma, b=k \cdot(3 / 2-y / 2)$, and using the inductive hypothesis,

$$
c=\lim _{t \rightarrow \infty} \frac{c_{t} \cdot t}{s_{t}}=(k-1)\left(\frac{3}{2}-\frac{y}{2}\right) M_{k-1} .
$$

Therefore, $M_{k}$ exists and

$$
M_{k}=\frac{(k-1)(3 / 2-y / 2) M_{k-1}}{k(3 / 2-y / 2)+\Gamma}=\frac{k-1}{k-1+\beta} M_{k-1}
$$

The proof of the following corollary follows exactly from [7]. We include the proof here for completeness.

Corollary 7.1 Under the assumptions in Theorem 7.1, $M_{k}$ is proportional to $k^{-\beta}$.
Proof. Consider Equation (7.6). It is a fact that a differentiable function $f$ is convex if and only if $f\left(x_{2}\right) \geq f\left(x_{1}\right)+f^{\prime}\left(x_{1}\right)\left(x_{2}-x_{1}\right)$ for every $x_{1}$ and $x_{2}$ [36]. Applying this with $\left(f(z), x_{1}, x_{2}\right)=\left(z^{\beta}, 1,1+1 / j\right)$, we get

$$
\begin{equation*}
\prod_{j=1}^{k-1} \frac{j}{j+\beta}=\prod_{j=1}^{k-1}(1+\beta / j)^{-1} \geq \prod_{j=1}^{k-1}(1+1 / j)^{-\beta}=k^{-\beta} \tag{7.7}
\end{equation*}
$$

Also though, applying this with $\left(f(z), x_{1}, x_{2}\right)=\left(z^{\beta}, 1,1-1 / j\right)$ we obtain

$$
\begin{equation*}
\prod_{j=1}^{k-1} \frac{j}{j+\beta}=\prod_{j=1}^{k-1}(1-\beta /(j+\beta))^{-1} \leq \prod_{j=1}^{k-1}(1-1 /(j+\beta))^{-\beta}=\left(\frac{\beta}{k-1+\beta}\right)^{\beta} \leq \beta^{\beta} \cdot k^{-\beta} \tag{7.8}
\end{equation*}
$$

Therefore, $c_{1} k^{\text {-beta }} \leq M_{k} \leq c_{2} k^{- \text {beta }}$ for some positive constants $c_{1}, c_{2}$ and every $k \geq 1$.
Finally, we can state which power-law exponents are obtainable.
Lemma 7.2 For any $x \in(1, \infty)$, there exists a choice of $p_{t}, r_{t}, q_{t}$ such that in $\operatorname{TGPA}\left(p_{t}, r_{t}, q_{t}\right)$ the resulting network follows a power law in the degree distribution with exponent $\beta=x$.

Proof. We can use three separate cases:
(i) For $x \in(5 / 3, \infty)$, setting $y_{t}=3-2 /(x-1)$ gives exponent $\beta=1+2 /(3-(3-2 /(x-1)))=x$.
(ii) For $x \in(1,5 / 3)$, set $y_{t}=t^{3 / 2(x-5 / 3)}$. Then

$$
\begin{aligned}
\Gamma & =\lim _{t \rightarrow \infty} \frac{y_{t+1} \cdot t}{\sum_{j=1}^{t} y_{j}}=\lim _{t \rightarrow \infty} \frac{(t+1)^{3 / 2(x-5 / 3)} \cdot t}{\sum_{j=1}^{t}\left(j^{3 / 2(x-5 / 3)}\right)}=\lim _{t \rightarrow \infty} \frac{\cdot t^{3 / 2 x-3 / 2}}{\int_{j=0}^{t} j^{3 / 2(x-5 / 3)} d j} \\
& =\lim _{t \rightarrow \infty} \frac{(3 / 2 x-3 / 2) t^{3 / 2 x-3 / 2}}{\left.j^{3 / 2 x-3 / 2}\right|_{j=0} ^{t}}=3 / 2 x-3 / 2
\end{aligned}
$$

and $\beta=1+(2 \Gamma) /(3-y)=1+2(3 / 2 x-3 / 2) /(3-0)=x$.
(iii) For $x=5 / 3$, set $y_{t}=1 / \ln (t+2)$ for every $t$. Then we have

$$
\Gamma=\lim _{t \rightarrow \infty} \frac{y_{t+1} \cdot t}{\sum_{j=1}^{t} y_{j}}=\lim _{t \rightarrow \infty} \frac{t / \ln (t+3)}{\sum_{j=1}^{t} 1 / \ln (j+2)}=\lim _{t \rightarrow \infty} \frac{t / \ln (t+3)}{t / \ln t}=1 .
$$

Then TGPA $\left(p_{t}, r_{t}, q_{t}\right)$ follows a power-law degree distribution with exponent $\beta=1+2 \Gamma /(3-y)=$ $1+2 /(3-0)=5 / 3$.

For a final analysis, we show that the component portion is necessary to obtain the full power-law exponent range $(1, \infty)$. Lemma 7.3 comes directly from [7].

Lemma 7.3 [7] Assume $\lim _{t \rightarrow \infty} y_{t}=y$ and $\lim _{t \rightarrow \infty} y_{t+1} \cdot t / \sum_{j=1}^{t} j_{j}=\Gamma$. Then for $y>0$ we have $\Gamma=1$, and for $y=0$ we have $\Gamma \leq 1$.

Corollary 7.2 Consider $\operatorname{TGPA}\left(p_{t}, r_{t}, q_{t}\right)$. Assume that $\lim _{t \rightarrow \infty} q_{t}=0, \lim _{t \rightarrow \infty} y_{t}=y$ and $y_{t+1} t / \sum_{j=1}^{t} y_{j}=$ $\Gamma>0$. Then the resulting graph follows a power-law degree distribution with exponent $\beta \in(1,3]$.

Proof. By Corollary 7.1, TGPA $\left(p_{t}, r_{t}, q_{t}\right)$ follows a power law in the degree distribution with exponent $\beta=1+2 \Gamma /(3-y)>1$. By Lemma 7.3, for $0<y \leq 1$, we have $\beta=1+2 /(3-y) \in(5 / 3,3]$ and for $y=0$, we have $\beta=1+2 \Gamma / 3 \leq 5 / 3$.

## 8. Conclusions and discussion

In this article, we presented a graph model called TGPA, which incorporates direct triangle formulation into a GPA model that includes possibly disconnected components. Furthermore, we provided extensive analysis of this model, showing that the degree and spectral distributions fit power-law distributions. We also extended the results for the GPA model found in [7] as well as the model defined in [4].

Our new model provides a useful platform for studying real-world network data. The importance of power laws in the spectra of real-world networks has been shown [8]; however, an explanation for why this feature occurs remains to be found. We hope that by introducing a model with this feature along with realistic clustering coefficients will lead to further explanation for the presence of highly skewed spectra. In the future, we plan to study further generalizations of higher-order PA graphs.

## Appendix A. GPA proofs

In this appendix, we provide proofs for theoretical results from Section 5.

Proof of Lemma 5.1. Denote $G_{t}^{m}$ as the graph at time $t$ with contractions of size $m$. Let $Z_{t}=d_{t}^{m}(s)$ be the degree of vertex $s$ at time $t$, and $Y_{t}$ an indicator for the event that the edge added at time $t$ is incident to $s$. Then,

$$
\begin{aligned}
\mathbb{E}\left[Z_{t}^{(k)}\right] & =\mathbb{E}\left[\mathbb{E}\left[\left(Z_{t-1}+Y_{t}\right)^{(k)}\right] \mid Z_{t-1}\right] \\
& =\mathbb{E}\left[Z_{t-1}^{(k)}\left(1-p \cdot \frac{Z_{t-1}}{2 t-1}\right)+\left(Z_{t-1}+1\right)^{(k)}\left(p \cdot \frac{Z_{t-1}}{2 t-1}\right)\right] \\
& =\mathbb{E}\left[Z_{t-1}^{(k)}\right]\left(1+\frac{p k}{2 t-1}\right)
\end{aligned}
$$

Next we apply this relationship iteratively, down to the time when node $s$ was added. Denote this as time $s^{\prime}$, and also note that the degree of $s$ at time $s^{\prime}$ is bounded by $2 m$ (if all m edges were added as self-loops)
to get

$$
\mathbb{E}\left(Z_{t}^{(k)}\right)=\prod_{t^{\prime}=s^{\prime}}^{t}\left(1+\frac{p k}{2 t^{\prime}-1}\right) \leq(2 m)^{(k)} \prod_{t^{\prime}=s^{\prime}+1}^{t}\left(1+\frac{p k}{2 t^{\prime}-1}\right)
$$

Use $1+x \leq e^{x}$ to write the product as a sum, and bound

$$
\sum_{t^{\prime}=s^{\prime}+1}^{t} \frac{1}{t^{\prime}-1 / 2} \leq \int_{x=s^{\prime}}^{t} \frac{1}{x-1 / 2} \mathrm{dx}=\log \frac{t-1 / 2}{s^{\prime}-1 / 2}
$$

So finally,

$$
\mathbb{E}\left(Z_{t}^{(k)}\right) \leq(2 m)^{(k)}\left(\frac{t-1 / 2}{s^{\prime}-1 / 2}\right)^{p k / 2}=(2 m)^{(k)}\left(\frac{t}{s^{\prime}}\right)^{p k / 2}\left(\frac{2-1 / t}{2-1 / s^{\prime}}\right)^{p k / 2}(2 m)^{(k)}\left(\frac{t}{s^{\prime}}\right)^{p k / 2} 2^{p k / 2} .
$$

Proof of Lemma 5.2. Let $\tau^{(i)}=\left(\tau_{1}^{(i)}, \ldots, \tau_{r_{i}}^{(i)}\right)$, where $\tau_{j}^{(i)}$ is the time when we add an edge incident to $S_{i}$ and increase the degree from $d_{i}+j-1$ to $d_{i}+j$. Define $\tau=\left(\tau_{0}, \tau_{1}, \ldots, \tau_{r+1}\right)$ to be the ordered union of $\tau^{(i)}$, with $\tau_{0}=t_{0}$ and $\tau_{r+1}=t$. Let $p\left(\tau ; \mathrm{d}, t_{0}, t\right)$ be the probability that $S_{i}$ increases in degree at exactly the times specified by $\tau$. Then

$$
\begin{aligned}
p\left(\tau ; \mathrm{d}, t_{0}, t\right) & =\left(\prod_{i=1}^{l} \prod_{k=1}^{r_{i}} p \frac{d_{i}+k-1}{2 \tau_{k}^{(i)}-1}\right)\left(\prod_{k=0}^{r} \prod_{j=\tau_{k}+1}^{\tau_{k+1}-1}\left(1-p \frac{d+k}{2 j-1}\right)\right) \\
& =\left(\prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!}\right)\left(\prod_{k=1}^{r} \frac{p}{2 \tau_{k}-1}\right) \exp \left\{\sum_{k=0}^{r} \sum_{j=\tau_{k}+1}^{\tau_{k+1}-1} \log \left(1-p\left(\frac{d+k}{2 j-1}\right)\right)\right\} .
\end{aligned}
$$

We can bound the inner most sum of the exponential term using a simple inequality

$$
\sum_{j=\tau_{k}+1}^{\tau_{k+1}-1} \log \left(1-p\left(\frac{d+k}{2 j-1}\right)\right) \leq \sum_{j=\tau_{k}+1}^{\tau_{k+1}-1} \log \left(1-\frac{p(d+k)}{2 j}\right)
$$

which is less than or equal to

$$
\begin{aligned}
\int_{\tau_{k}+1}^{\tau_{k+1}} \log \left(1-\frac{p(d+k)}{2 x}\right) \mathrm{dx} & =-\tau_{k+1} \log \left(2 \tau_{k+1}\right)+\left(\tau_{k}+1\right) \log \left(2 \tau_{k}+2\right) \\
& -1 / 2\left(2 \tau_{k+1}-p(d+k)\right) \log \left(2 \tau_{k+1}-p(d+k)\right) \\
& -1 / 2\left(2 \tau_{k}+2-p(d+k)\right) \log \left(2 \tau_{k}+2-p(d+k)\right)
\end{aligned}
$$

Note that $\tau_{0}=t_{0}$ and $\tau_{r+1}=t$. Then we can write

$$
\sum_{k=0}^{r} \int_{\tau_{k}+1}^{\tau_{k+1}} \log \left(1-\frac{p(d+k)}{2 x}\right) \mathrm{dx}=A+\sum_{k=1}^{r} B_{k}
$$

where

$$
\begin{align*}
A & =\left(t_{0}+1\right) \log \left(2 t_{0}+2\right)-1 / 2\left(2 t_{0}+2-p d\right) \log \left(2 t_{0}+2-p d\right)  \tag{A.1}\\
& -t \log (2 t)+1 / 2(2 t-p(d+r)) \log (2 t-p(d+r))
\end{align*}
$$

and

$$
\begin{align*}
B_{k}= & \tau_{k} \log \left(1+1 / \tau_{k}\right)+\log \left(2 \tau_{k}+2\right)-\frac{2-p}{2} \log \left(2 \tau_{k}+p-p(d+k)\right) \\
& +1 / 2\left(2 \tau_{k}+2-p(d+k)\right) \log \left(1-\frac{2-p}{2 \tau_{k}+2-p(d+k)}\right) \tag{A.2}
\end{align*}
$$

Bound each of $A$ and $B_{k}$, starting with $B_{k}$. Since $1+x \leq e^{x}, \tau_{k} \log \left(1+1 / \tau_{k}\right) \leq 1$ and $\frac{1}{2}\left(2 \tau_{k}+2-p(d+\right.$ k)) $\log \left(1-\frac{2-p}{2 \tau_{k}+2-p(d+k)}\right) \leq-p / 2$. Rearranging the other two terms of Equation (A.2), we get

$$
B_{k} \leq \frac{p}{2} \log \left(2 \tau_{k}+2\right)-\frac{2-p}{2} \log \left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)+\frac{p}{2} .
$$

Rearranging terms of $A$ from Equation (A.1) and taking the exponential,

$$
\begin{aligned}
e^{A} & =\left(1-\frac{p d}{2 t_{0}+2}\right)^{-\left(t_{0}+1\right)}\left(2 t_{0}+2-p d\right)^{p d / 2}\left(1-\frac{p(d+r)}{2 t}\right)^{t}(2 t-p(d+r))^{\frac{-p(d+r)}{2}} \\
& =\left(1-\frac{p d}{2 t_{0}+2}\right)^{-\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)\left(t_{0}+1\right)}\left(1-\frac{p(d+r)}{2 t}\right)^{t-\frac{p(d+r)}{2}}\left(\frac{t_{0}+1}{t}\right)^{\frac{p d}{2}}(2 t)^{\frac{-p r}{2}} .
\end{aligned}
$$

Using the bound $1-x \leq e^{-x-x^{2} / 2}$ for $0<x<1$,

$$
\left(1-\frac{p(d+r)}{2 t}\right)^{t-p(d+r) / 2} \leq \exp \left\{-\frac{p(d+r)}{2}+\frac{p^{2}(d+r)^{2}}{8 t}+\frac{p^{3}(d+r)^{3}}{16 t^{2}}\right\}
$$

Putting the bounds on $A$ and $B_{k}$ together, we get

$$
\begin{align*}
e^{A+\sum B_{k}} \leq & \left(1-\frac{p d}{2 t_{0}+2}\right)^{-\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)\left(t_{0}+1\right)} \exp \left\{-\frac{p(d+r)}{2}+\frac{p^{2}(d+r)^{2}}{8 t}+\frac{p^{3}(d+r)^{3}}{16 t^{2}}\right\}  \tag{A.3}\\
& \times\left(\frac{t_{0}+1}{t}\right)^{p d / 2}(2 t)^{-p r / 2} \prod_{k=1}^{r}\left(\left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)^{-(2-p) / 2}\left(2 \tau_{k}+2\right)^{p / 2}\right) e^{p r / 2} .
\end{align*}
$$

Define $\operatorname{err}\left(r, d, t_{0}, t\right)$

$$
\operatorname{err}\left(r, d, t_{0}, t\right)=\left(1-\frac{p d}{2 t_{0}+2}\right)^{-\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)\left(t_{0}+1\right)} \exp \left\{-\frac{p d}{2}+\frac{p^{2}(d+r)^{2}}{8 t}+\frac{p^{3}(d+r)^{3}}{16 t^{2}}\right\}
$$

then we can rewrite Equation (A.3) as

$$
\operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{\frac{p d}{2}}(2 t)^{\frac{-p r}{2}} \prod_{k=1}^{r}\left(\left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)^{\frac{-(2-p)}{2}}\left(2 \tau_{k}+2\right)^{\frac{p}{2}}\right)
$$

So, we finally finish with the bound on $p\left(\tau ; \mathrm{d}, t_{0}, t\right)$ by substituting Equation (A.3) into Equation (A.1) and rearranging terms:

$$
\begin{aligned}
p\left(\tau ; \mathrm{d}, t_{0}, t\right)= & \left(\prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!}\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d / 2}(2 t)^{-p r / 2} \\
& \times \prod_{k=1}^{r}\left(p\left(2 \tau_{k}+p-p(d+k)\right)^{-(2-p) / 2}\left(1+\frac{3}{2 \tau_{k}-1}\right)\right)
\end{aligned}
$$

Now sum $p\left(\tau ; \mathrm{d}, t_{0}, t\right)$ over all ordered choices of $\tau$ to get

$$
\left.\left.\left.\begin{array}{c}
p\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right) \leq \sum_{\tau^{(1), \ldots, \tau^{(l)}}} p\left(\tau ; \mathrm{d}, t_{0}, t\right) \\
\leq\binom{ r}{r_{1}, \ldots, r_{l}}_{t_{0}+1 \leq \tau_{1}<\ldots<\tau_{r} \leq t} \prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!} \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{\frac{p d}{2}} \\
\\
\times(2 t)^{\frac{-p r}{2}} p \prod_{k=1}^{r}\left(2 \tau_{k}+p-p(d+k)\right)^{-(2-p) / 2}\left(1+\frac{3}{2 \tau_{k}-1}\right) \\
=r!\left(\prod _ { i = 1 } ^ { l } \left(r_{i}+d_{i}-1\right.\right.  \tag{A.4}\\
d_{i}-1
\end{array}\right)\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d / 2}(2 t)^{-p r / 2}\right) \quad \sum_{t_{0}+1 \leq \tau_{1}<\ldots<\tau_{r} \leq t} p \prod_{k=1}^{r}\left(2 \tau_{k}+p-p(d+k)\right)^{-(2-p) / 2}\left(1+\frac{3}{2 \tau_{k}-1}\right) .
$$

Now let $\tau_{k}^{\prime}=\tau_{k}-\lceil p(d+k) / 2\rceil$. Since $d \geq 1$ and $k \geq 1$, we have $2\lceil p(d+k) / 2\rceil \geq 2$. So Equation (A.4) is less than or equal to

$$
\begin{aligned}
\sum_{\left(t_{0}-p\lceil d / 2\rceil+1\right) \leq \tau_{1}^{\prime} \leq \ldots \leq \tau_{r}^{\prime} \leq(t-p\lceil(d+r) / 2\rceil)} & \left(p \prod_{k=1}^{r}\left(2 \tau_{k}^{\prime}+p\right)^{-(2-p) / 2}\left(1+\frac{3}{2 \tau_{k}^{\prime}+1}\right)\right) \\
& \left.\leq \frac{p}{r!}\left(\sum_{\tau^{\prime}=\left(t_{0}-p\lceil d / 2\rceil+1\right)}^{t-p\lceil(d+r) / 2\rceil}\left(2 \tau^{\prime}+p\right)^{-(2-p) / 2}+3\left(2 \tau^{\prime}+1\right)^{-(4-p) / 2}\right)\right)^{r}
\end{aligned}
$$

$$
=\frac{1}{r!}(2 t)^{p r / 2} \underbrace{\left(1-\frac{p(d+r)-p}{2 t}\right)^{p r / 2}}_{\leq \exp \left\{-\frac{r p(p(d+r)-p)}{4 t}\right\}} \underbrace{\left(1+\frac{3 p}{(2 t-p(d+r)+p)^{p / 2}}\right)^{r}}_{\leq \exp \left\{\frac{3 p r}{(2 t-p(d+r)+p)^{p / 2}}\right\}} .
$$

Where the last inequalities come from $1+x \leq e^{x}$. So finally,

$$
\begin{aligned}
p_{S}\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right) \leq & \left(\prod_{i=1}^{l}\binom{r_{i}+d_{i}-1}{d_{i}-1}\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d / 2} \\
& \exp \left\{\frac{-r p((d+r)-p)}{4 t}+\frac{3 p r}{(2 t-p(d+r)+p)^{p / 2}}\right\} .
\end{aligned}
$$

Using $d=o\left(t^{1 / 2}\right)$ and $r=o\left(t^{2 / 3}\right)$ gives the final bound, and this concludes the proof.
Proof of Theorem 5.1. Partition the vertices into those added before time $t_{0}$, before time $t_{1}$, and after $t_{1}$, with $t_{0}=\log \log \log f(t), t_{1}=\log \log f(t)$. We will argue about the maximum degree vertices in each set.

Claim A. 1 In $G_{t}^{m}$, the degree of the supernode of vertices added before time $t_{0}$ is at least $t_{0}^{1 / 3} t^{p / 2}$ whp.
Proof. Consider all vertices added before time $t_{0}$ as a supernode. Let $A_{1}$ denote the event that this supernode has degree less than $t_{0}^{1 / 3} t^{p / 2}$ at time $t$. Use Lemma 5.2 with $l=1$, and $d=2 t_{0}$ to bound

$$
\operatorname{Pr}\left[A_{1}\right] \leq \sum_{r_{1}=0}^{t_{0}^{1 / 3} t^{p / 2}-2 t_{0}}\binom{r_{1}+2 t_{0}-1}{2 t_{0}-1}\left(\frac{t_{0}+1}{t}\right)^{p d / 2} e^{2+t_{0}-p d / 2+3 p r / t^{p / 2}}
$$

Then, since $r \leq t_{0}^{1 / 3} t^{1 / 2}-2 t_{0}$,

$$
\operatorname{Pr}\left[A_{1}\right] \leq \sum_{r_{1}=0}^{t_{0}^{1 / 3} t^{p / 2}-2 t_{0}}\binom{t_{0}^{1 / 3} t^{p / 2}-1}{2 t_{0}-1}\left(\frac{t_{0}+1}{t}\right)^{p t_{0}} e^{2+t_{0}-p t_{0}+3 p t_{0}^{1 / 3}-6 p t_{0} / t^{p / 2}}
$$

Replacing the sum with $\left(t_{0}^{1 / 3} t^{p / 2}-2 t_{0}\right)$, and the using the definition of the combination,

$$
\operatorname{Pr}\left[A_{1}\right] \leq\left(t_{0}^{1 / 3} t^{p / 2}-2 t_{0}\right) \frac{\left(t_{0}^{1 / 3} t^{p / 2}-1\right)!}{\left(2 t_{0}-1\right)!\left(t_{0}^{1 / 3} t^{p / 2}-2 t_{0}\right)!}\left(\frac{t_{0}+1}{t}\right)^{p t_{0}} e^{2+t_{0}(1-p)+3 p t_{0}^{1 / 3}-6 p t_{0} / t^{p / 2}}
$$

And finally, by writing out $\left(t_{0}^{1 / 3} t^{p / 2}-1\right)!/\left(t_{0}^{1 / 3} t^{p / 2}-2 t_{0}\right)$ !, we can reduce the expression further as

$$
\operatorname{Pr}\left[A_{1}\right] \leq t_{0}^{1 / 3} t^{p / 2} \frac{\left(t_{0}^{1 / 3} t^{p / 2}\right)^{2 t_{0}-1}}{\left(2 t_{0}-1\right)!}\left(\frac{t_{0}+1}{t}\right)^{p t_{0}} e^{2+t_{0}(1-p)+3 p t_{0}^{1 / 3}-6 p t_{0} / t^{p / 2}}
$$

Using $1 / x \leq e^{x} / x^{x}$ and rearranging terms, $P\left[A_{1}\right]$ goes to 0

$$
\operatorname{Pr}\left[A_{1}\right] \leq \frac{e^{1+(3-p) t_{0}+3 p t_{0}^{1 / 3}-6 p t_{0} / t / 2}}{\left(2 t_{0}-1\right)^{t_{0}(4 / 3-p)-1}}
$$

Claim A. 2 In $G_{t}^{m}$, no vertex added after time $t_{1}$ has degree exceeding $t_{0}^{-2} t^{p / 2}$ whp.
Proof. Let $A_{2}$ denote the event that some vertex added after time $t_{1}$ has degree exceeding $t_{0}^{-2} t^{p / 2}$. Write the probability of $A_{2}$ occurring as

$$
\begin{align*}
\operatorname{Pr}\left[A_{2}\right] & \leq \sum_{s=t_{1}}^{t} \operatorname{Pr}\left[d_{t}(s) \geq t_{0}^{-2} t^{p / 2}\right]=\sum_{s=t_{1}}^{t} \operatorname{Pr}\left[\left(d_{t}(s)\right)^{(l)} \geq\left(t_{0}^{-2} t^{p / 2}\right)^{(l)}\right] \\
& \leq \sum_{s=t_{1}}^{t} t_{0}^{t^{2 l} t^{-l p / 2} \mathbb{E}\left[\left(d_{t}(s)\right)^{(l)}\right]=\sum_{s=t_{1}}^{t} t_{0}^{2 l} t^{-l p / 2}(2 m)^{(l)} 2^{l_{p / 2}}\left(\frac{t}{s}\right)^{l p / 2}} \\
& =2^{l p / 2}(2 m)^{(l)} t_{0}^{2 l} \int_{t_{1}-1}^{t} x^{-l p / 2} \mathrm{dx} . \tag{A.5}
\end{align*}
$$

Compute the integral in Equation (A.5)

$$
\begin{equation*}
\int_{t_{1}-1}^{t} x^{-l p / 2} \mathrm{dx}=\left.\frac{x^{-l p / 2+1}}{-l p / 2+1}\right|_{t_{1}-1} ^{t}=(-l p / 2+1)^{-1}\left(t^{-l p / 2+1}-\left(t_{1}-1\right)^{-l p / 2+1}\right) \tag{A.6}
\end{equation*}
$$

Choose $l>2 / p$. Then the integral in Equation (A.6) is less than or equal to $(l p / 2-1)^{-1}\left(t_{1}-1\right)^{-l p / 2+1}$, and plugging in the computation from Equation (A.6) into Equation (A.5),

$$
\operatorname{Pr}\left[A_{2}\right] \leq \frac{2^{l p / 2}(2 m)^{(l)} t_{0}^{2 l}}{(l p / 2-1)\left(t_{1}-1\right)^{l p / 2-1}}
$$

which goes to 0 as $t$ increases.
CLaim A. 3 In $G_{t}^{m}$, no vertex added before time $t_{1}$ has degree exceeding $t_{0}^{1 / 6} t^{p / 2}$ whp.
Proof. Use same technique as in Claim A.2.
CLaIm A. 4 The k highest degree vertices of $G_{t}^{m}$ are added before time $t_{1}$ and have degree $\Delta_{i}$ bounded by $t_{0}^{-1} t^{p / 2} \leq \Delta_{i} \leq t_{0}^{1 / 6} t^{p / 2}$.

Proof. If the lower bound does not hold, then one of the top $k$ vertices has degree less than $t_{0}^{-1} t^{p / 2}$ and the total degree of vertices added before time $t_{0}$ is bounded by

$$
\begin{aligned}
& (k-1) t_{0}^{1 / 6} t^{p / 2}+\left(\frac{t_{0}}{m}-k+1\right)\left(t_{0}^{-1} t^{p / 2}\right) \leq k t_{0}^{1 / 6} t^{p / 2}+t_{0}\left(t_{0}^{-1} t^{p / 2}\right) \\
& =k t_{0}^{1 / 6} t^{p / 2}+t^{p / 2}=t^{p / 2}\left(k t_{0}^{1 / 6}+1\right) \leq t^{p / 2}\left(2 k t_{0}^{1 / 6}\right) \leq t^{p / 2} t_{0}^{1 / 3}
\end{aligned}
$$

Since we have the lower bound, and we know that $t^{p / 2} / t_{0} \geq t^{p / 2} / t_{0}^{2}$, none of the largest degree vertices could be added after time $t_{1}$.

CLaim A. 5 The $k$ highest degree vertices have $\Delta_{i} \leq \Delta_{i-1}-\frac{t^{p / 2}}{f(t)}$ whp.
Proof. Let $A_{4}$ denote the event that there are two vertices among the first $t_{1}$ time steps with degrees exceeding $t_{0}^{-1} t^{p / 2}$ and within $t^{p / 2} / f(t)$ of each other. Let $\bar{A}_{3}$ be the opposite of event $A_{3}$ from Claim A.3. Let

$$
\begin{equation*}
p_{l, s_{1}, s_{2}}=\operatorname{Pr}\left[d_{t}\left(s_{1}\right)-d_{t}\left(s_{2}\right)=l \mid \bar{A}_{3}\right], \text { for }|l| \leq t^{p / 2} / f(t) . \tag{A.7}
\end{equation*}
$$

Then,

$$
\begin{aligned}
\operatorname{Pr}\left[A_{4} \mid \bar{A}_{3}\right] & \leq \sum_{1 \leq s_{1}<s_{2} \leq t_{1}} \sum_{l=-t^{p / 2} / f(t)}^{t^{p / 2} / f(t)} p_{l, s_{1}, s_{2}} \\
p_{l, s_{1}, s_{2}} & \leq \sum_{r_{1}=t_{0}^{-1} t^{p / 2} / 2}^{t_{0}} \sum_{d_{1}, d_{2}=1}^{t_{0}^{1 / t_{t} / 2}} p_{\left(s_{1}, s_{2}\right)}\left(\left(r_{1}, r_{1}-l\right) ;\left(d_{1}, d_{2}\right), t_{1}, t\right) \\
& \left.\leq \sum_{r_{1}=t_{0}^{-1} t_{t} t^{p / 2} / 2}^{t_{0}^{1 / 6} \sum_{d_{1}, d_{1} / 2}} \sum_{d_{2}=1}^{2 t_{1}}\binom{r_{1}+d_{1}-1}{d_{1}-1}\binom{r_{1}-l+d_{2}-1}{d_{2}-1}\left(\frac{t_{1}+1}{t}\right)^{\frac{p\left(d_{1}+d_{2}\right)}{2}} e^{\left\{+t_{1}-\frac{p\left(d_{1}+d_{2}\right)}{2}+\frac{3 p\left(r_{1}-l\right)}{t^{p / 2}}\right\}}\right\} \\
& \leq t_{0}^{1 / 6} t^{p / 2} \sum_{d_{1}, d_{2}=1}^{2 t_{1}}\left(2 t_{0}^{1 / 6} t^{p / 2}\right)^{d_{1}+d_{2}-2}\left(t_{1}+1\right)^{2 p t_{1}} t^{-p\left(d_{1}+d_{2}\right) / 2} e^{2+t_{1}+3 p t_{0}^{1 / 6}} \\
& =t^{-p / 2} t_{0}^{1 / 6}\left(2 t_{1}\right)^{2} 2^{4 t_{1}} t_{0}^{2 t_{1} / 3}\left(t_{1}+1\right)^{2 p t_{1}} e^{2+t_{1}+3 p t_{0}^{1 / 6}} .
\end{aligned}
$$

Denote the last equation as $h(t)$ and note $h(t)$ is a polynomial in $\log (f(t))$ times a factor of $t^{-p / 2}$. Then going back to Equation (A.7),

$$
\operatorname{Pr}\left[A_{4} \mid \bar{A}_{3}\right] \leq\binom{ t_{1}}{2} 2 \frac{t^{p / 2}}{f(t)} h(t)=\binom{t_{1}}{2} 2 \frac{\operatorname{poly}(\log (f(t)))}{f(t)}
$$

which goes to 0 as $t$ increases.
Finishing that final Claim finishes the proof of the theorem.
Proof of Theorem 5.2. Let $G=G_{t}^{m}$. We will show that with high probability $G$ contains a star forest $F$, with stars of degree asymptotic to the maximum degree vertices of $G$. Then show that $G \backslash F$ has small eigenvalues. Then we can use Rayleigh's principle to say that the large eigenvalues of $G$ cannot be too different than the large eigenvalues of $F$.

Let $S_{i}$ be the vertices added after time $t_{i-1}$ and at or before time $t_{i}$, for $t_{0}=0, t_{1}=t^{1 / 8}, t_{2}=t^{9 / 16}, t_{3}=t$. We start by finding bounds on the degrees of $G$.

CLaim A. 6 For any $\varepsilon>0$, and any $f(t)$ with $f(t) \rightarrow \infty$ as $t \rightarrow \infty$ the following holds whp: for all $s$ with $f(t) \leq s \leq t$, for all vertices $v \in G_{s}$, if $v$ was added at time $r$, then $d_{s}(v) \leq s^{p / 2+\varepsilon} r^{-p / 2}$.

Proof. We prove this by contradiction. Bound the probability that $d_{s}^{m}(r)$ is greater than $s^{p / 2+\varepsilon} r^{-p / 2}$ :

$$
\begin{aligned}
\operatorname{Pr} & {\left[\cup_{s=f(t)}^{t} \cup_{r=1}^{s}\left\{d_{s}^{m}(r) \geq s^{p / 2+\varepsilon} r^{-p / 2}\right\}\right] \leq \sum_{s=f(t)}^{t} \sum_{r=1}^{s} \operatorname{Pr}\left[d_{s}^{m}(r) \geq s^{p / 2+\varepsilon} r^{-p / 2}\right] } \\
& =\sum_{s=f(t)}^{t} \sum_{r=1}^{s} \operatorname{Pr}\left[\left(d_{s}^{m}(r)\right)^{(l)} \geq\left(s^{p / 2+\varepsilon} r^{-p / 2}\right)^{(t)}\right]
\end{aligned}
$$

which is bounded using Markov:

$$
\leq \sum_{s=f(t)}^{t} \sum_{r=1}^{s} s^{-l(p / 2+\varepsilon)} r^{p l / 2} \mathbb{E}\left[\left(d_{s}^{m}(r)\right)^{(l)}\right],
$$

and which we can bound using Lemma 5.1

$$
\leq \sum_{s=f(t)}^{t} \sum_{r=1}^{s} s^{l(p / 2+\varepsilon)} r^{l p / 2}(2 m)^{(l)} 2^{l p / 2}\left(\frac{s}{r}\right)^{l p / 2}=(2 m)^{(l)} 2^{l p / 2} \sum_{s=f(t)}^{t} s^{1-\varepsilon l} .
$$

Take $l \geq 3 / \varepsilon$. Then we can bound the sum by an integral,

$$
\sum_{s=f(t)}^{t} s^{1-\varepsilon l} \leq \int_{f(t)-1}^{\infty} x^{1-\varepsilon l} \mathrm{dx}=\left.\frac{1}{2-\varepsilon l} x^{2-\varepsilon l}\right|_{f(t)-1} ^{\infty}=\frac{1}{\varepsilon l-2}(f(t)-1)^{2-\varepsilon l},
$$

which goes to zero as $t$ increases, since $l \geq 3 / \varepsilon$.
Claim A. 7 Let $S_{3}^{\prime}$ be the set of vertices in $S_{3}$ that are adjacent to more than one vertex of $S_{1}$ in $G$. Then $\left|S_{3}^{\prime}\right| \leq t^{7 p / 16}$ with high probability.

Proof. Let $B_{1}$ be the event that the conditions of Claim A. 6 hold with $f(t)=t_{2}$ and $\varepsilon=1 / 16$. Then for a vertex $v \in S_{3}$ added at time $s$, the probability that $v$ picks at least one neighbour in $S_{1}$ is less than or equal to

$$
\frac{\sum_{w \in S_{1}} d_{s}(w)}{2 s-1} \leq \frac{\sum_{w \in S_{1}} s^{p / 2+\varepsilon}}{2 s-1}=\frac{t_{1} s^{p / 2+\varepsilon}}{2 s-1}
$$

Then the probability of having two or more neighbours in $S_{1}$ can be bounded by

$$
\operatorname{Pr}\left[\left|N(v) \cap S_{1}\right| \geq 2 \mid B_{1}\right] \leq\left(\frac{t_{1} s^{p / 2+\varepsilon}}{2 s-1}\right)^{2} \cdot\binom{m}{2} \leq m^{2} t^{1 / 4} s^{(-15+8 p) / 8}
$$

Let $X$ denote the number of $v \in S_{3}$ adjacent to more than one vertex of $S_{1}$. Then

$$
\begin{aligned}
\mathbb{E}\left[X \mid B_{1}\right] & \leq \sum_{t_{2}+1}^{t} m^{2} s^{(-15+8 p) / 8} t^{1 / 4} \leq m^{2} t^{1 / 4} \int_{t_{2}}^{t} x^{(-15+8 p) / 8} \mathrm{dx} \\
& =m^{2} t^{1 / 4}\left[\left.\frac{8}{7+8 p} x^{(-7+8 p) / 8}\right|_{t_{2}} ^{t}\right] \leq \frac{8 m^{2} t^{1 / 4}}{-7+8 p} t^{(-7+8 p) / 8} .
\end{aligned}
$$

Then by Markov,

$$
\operatorname{Pr}\left[X \geq t^{7 p / 16} \mid B_{1}\right] \leq \frac{\mathbb{E}\left[X \mid B_{1}\right]}{t^{7 p / 16}} \leq \frac{8 m^{2}}{8 p-7} \frac{t^{p-5 / 8}}{t^{7 p / 16}}=\frac{8 m^{2}}{8 p-7} \frac{t^{-5 / 8}}{t^{-9 p / 16}}
$$

and $\frac{t^{-5 / 8}}{t^{-9 p / 16}}=\frac{t^{9 p / 16}}{t^{5 / 8}} \leq \frac{t^{9 / 16}}{t^{5 / 8}}$ which goes to zero.
Let $F \subseteq G$ be the star forest consisting of edges between $S_{1}$ and $S_{3} \backslash S_{3}^{\prime}$.
Claim A. 8 Let $\Delta_{1} \geq \Delta_{2} \geq \ldots \geq \Delta_{k}$ denote the degrees of the $k$ highest degree vertices of $G$. Then $\lambda_{i}(F)=(1-o(1)) \Delta_{i}^{1 / 2}$.

Proof. Denote $K_{1, d_{i}}$ to be a star of degree $d_{i}$. Let $H$ be the star forest $H=K_{1, d_{1}} \cup \ldots \cup K_{1, d_{k}}$ with $d_{1} \geq d_{2} \geq \ldots \geq d_{k}$. Then for $i=1, \ldots, k, \lambda_{i}(H)=d_{i}^{1 / 2}$. So it will be sufficient to show that $\Delta_{i}(F)=(1-o(1)) \Delta_{i}(G)$. Within the proof of Theorem 5.1, we show that the $k$ highest degree vertices $G$ are added before time $t_{1}$ (specifically in Claim A.4). So these vertices are all in $F$. The only edges to those vertices that are not in $F$ are those added before time $t_{2}$ and those incident to $S_{3}^{\prime}$.

By Theorem 5.1, we can choose $f(t)$ such that $\Delta_{1}\left(G_{t_{2}}^{m}\right) \leq t_{2}^{p / 2} f(t) \leq t^{7 p / 16}$. Additionally by Theorem 5.1, we get $\Delta_{i}(G) \geq t^{p / 2} / \log t$. Finally, Claim A. 7 says that $\left|S_{3}^{\prime}\right| \leq t^{7 p / 16}$ whp. So with high probability,

$$
\begin{aligned}
& \Delta_{i}(F) \geq \Delta_{i}(G)-t^{7_{p / 16}}-m t^{7_{p / 16}} \geq \frac{t^{p / 2}}{\log t}-t^{7_{p / 16}}(1+m)=\frac{t^{p / 2}}{\log t}\left[1-t^{7_{p / 16}}(1+m) \frac{\log t}{t^{p / 2}}\right] \\
& =\frac{t^{p / 2}}{\log t}\left[1-(1+m) \frac{\log t}{t^{p / 2-7 p / 16}}\right]=\frac{t^{p / 2}}{\log t}\left[1-(1+m) \frac{\log t}{t^{p / 16}}\right]=(1-o(1)) \Delta_{i}(G) .
\end{aligned}
$$

Let $H=G \backslash F$. Denote $\boldsymbol{A}_{G}, \boldsymbol{A}_{F}$ and $\boldsymbol{A}_{H}$ to be the adjacency matrices for graphs $G, F$ and $H$. In the following claim, we'll show that $\lambda_{1}\left(\boldsymbol{A}_{H}\right)$ is $o\left(\lambda_{k}\left(\boldsymbol{A}_{F}\right)\right)$. Consider the fact that if $\boldsymbol{A}$ and $\boldsymbol{A}+\boldsymbol{E}$ are symmetric $n$ by $n$ matrices, then $\lambda_{k}(\boldsymbol{A})+\lambda_{n}(\boldsymbol{E}) \leq \lambda_{k}(\boldsymbol{A})+\lambda_{1}(\boldsymbol{E})$ (see for instance [37]). That implies that for any subspace $L$,

$$
\max _{\mathrm{x} \in L, \mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{G} \mathrm{X}}{\mathrm{x}^{\top} \mathrm{x}}=\max _{\mathrm{x} \in L, \mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{F} \mathrm{X}}{\mathrm{x}^{\top} \mathrm{x}} \pm O\left(\max _{\mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{H} \mathrm{x}}{\mathrm{x}^{\top} \mathrm{x}}\right) .
$$

This is enough to finish the proof because by the Courant-Fischer Minimax Theorem ([37], Theorem 8.1.2), $\lambda_{i}\left(\boldsymbol{A}_{G}\right)=\lambda_{i}\left(\boldsymbol{A}_{F}\right)(1 \pm o(1))$.

Claim A. $9 \lambda_{1}\left(\boldsymbol{A}_{H}\right) \leq 6 m t^{15 / 64} \mathrm{whp}$.
Proof. Let $H_{i}$ denotes the subgraph of $H$ induced by $S_{i}$, and let $H_{i j}$ denotes the subgraph of $H$ containing only edges with one vertex in $S_{i}$ and the other in $S_{j}$. That is, write $\boldsymbol{A}_{H}$ in the following way:

$$
\boldsymbol{A}_{H}=\left[\begin{array}{ccc}
\boldsymbol{H}_{1} & \boldsymbol{H}_{12} & \boldsymbol{H}_{13} \\
\boldsymbol{H}_{21} & \boldsymbol{H}_{2} & \boldsymbol{H}_{23} \\
\boldsymbol{H}_{31} & \boldsymbol{H}_{32} & \boldsymbol{H}_{3}
\end{array}\right]
$$

and use this to bound the maximal eigenvalue of $\boldsymbol{A}_{H}$ as

$$
\begin{aligned}
\lambda_{1}\left(\boldsymbol{A}_{H}\right) & =\lambda_{1}\left(\left[\begin{array}{ccc}
\boldsymbol{H}_{1} & \boldsymbol{H}_{12} & \boldsymbol{H}_{13} \\
\boldsymbol{H}_{21} & \boldsymbol{H}_{2} & \boldsymbol{H}_{23} \\
\boldsymbol{H}_{31} & \boldsymbol{H}_{32} & \boldsymbol{H}_{3}
\end{array}\right]\right) \\
& \leq \lambda_{1}\left(\boldsymbol{H}_{1}\right)+\lambda_{1}\left(\boldsymbol{H}_{2}\right)+\lambda_{1}\left(\boldsymbol{H}_{3}\right)+\lambda_{1}\left(\boldsymbol{H}_{12}\right)+\lambda_{1}\left(\boldsymbol{H}_{23}\right)+\lambda_{1}\left(\boldsymbol{H}_{13}\right) .
\end{aligned}
$$

Note that the maximum eigenvalue of a graph is at most the maximum degree of a graph. By Claim A. 6 with $f(t)=t_{1}$ and $\varepsilon=1 / 64$,

$$
\begin{aligned}
& \lambda_{1}\left(\boldsymbol{H}_{1}\right) \leq \Delta_{1}\left(\boldsymbol{H}_{1}\right)=\max _{v \leq t_{1}}\left\{d_{t_{1}}^{m}(v)\right\} \leq t_{1}^{p / 2+\varepsilon} \leq t^{33 / 512} \\
& \lambda_{1}\left(\boldsymbol{H}_{2}\right) \leq \Delta_{1}\left(\boldsymbol{H}_{2}\right) \leq \max _{t_{1} \leq v \leq t_{2}}\left\{d_{t_{2}}^{m}(v)\right\} \leq t_{2}^{p / 2+\varepsilon} / t_{1}^{p / 2} \leq t^{233 / 1024} \\
& \lambda_{1}\left(\boldsymbol{H}_{3}\right) \leq \Delta_{1}\left(\boldsymbol{H}_{3}\right) \leq \max _{t_{2} \leq v \leq t_{3}}\left\{d_{t_{3}}^{m}(v)\right\} \leq t_{3}^{p / 2+\varepsilon} / t_{2}^{p / 2} \leq t^{15 / 64} .
\end{aligned}
$$

To bound $\lambda_{1}\left(\boldsymbol{H}_{i j}\right)$, start with $m=1$. For $i<j$, this implies that each vertex in $S_{j}$ has at most one edge in $\boldsymbol{H}_{i j}$, that is $H_{i j}$ is a star forest. Then we have a bound on $\boldsymbol{H}_{i j}$ by Claim A.8. For $m>1$, let $G^{\prime}$ be one of our generated graphs with $t$ edges and $m=1$. Think now of contracting vertices in $G^{\prime}$ (only the ones added using PA) into a single vertex. We can write $\boldsymbol{A}_{G}$ in terms of $\boldsymbol{A}_{G}^{\prime}: \boldsymbol{A}_{G}=\boldsymbol{C}^{\top} \boldsymbol{A}_{G}^{\prime} \boldsymbol{C}$, where $\boldsymbol{C}$ is a contraction matrix with $t$ rows and the number of columns equal to the number of vertices in $\boldsymbol{A}_{G}$ (at most $t / m$ ). The $i$ th column is equal to 1 at indices $j$ in which $(i, j)$ are identified. Similarly, we can write $\boldsymbol{H}_{i j}$ in terms of $\boldsymbol{H}_{i j}^{\prime}$.

Note that if $\mathrm{y}=\boldsymbol{C} \mathrm{x}$, then $\mathrm{y}^{\top} \mathrm{y}=\mathrm{x}^{\top} \boldsymbol{C}^{\top} \boldsymbol{C} \mathrm{x}$, where $\boldsymbol{C}^{\top} \boldsymbol{C}$ is a diagonal matrix with $1^{\prime} s$ and $m^{\prime}$ s on the diagonal. So $\mathrm{x}^{\top} \mathrm{x} \leq \mathrm{y}^{\top} \mathrm{y} \leq m \mathrm{x}^{\top} \mathrm{x}$ which we use to bound $\lambda_{1}\left(H_{i j}\right)$ as

$$
\begin{align*}
\lambda_{1}\left(\boldsymbol{H}_{i j}\right) & =\max _{\mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{H}_{i j} \mathrm{x}}{\mathrm{x}^{\top} \mathrm{x}}=\max _{\mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{C}^{\top} \boldsymbol{H}_{i j}^{\prime} \boldsymbol{C} \mathrm{x}}{\mathrm{x}^{\top} \mathrm{x}}=\max _{\mathrm{x} \neq 0, \mathrm{y}=\boldsymbol{C} \mathrm{x}} \frac{\mathrm{y}^{\top} \boldsymbol{H}_{i j}^{\prime} \mathrm{y}}{\mathrm{x}^{\top} \mathrm{x}} \\
& =\max _{\mathrm{x} \neq 0, \mathrm{y}=C \mathrm{x}} \frac{m \mathrm{y}^{\top} \boldsymbol{H}_{i j}^{\prime} \mathrm{y}}{m \mathrm{x}^{\top} \mathrm{x}} \leq \max _{\mathrm{x} \neq 0, \mathrm{y}=C \mathrm{x}} \frac{m \mathrm{y}^{\top} \boldsymbol{H}_{i j \mathrm{j}}^{\prime} \mathrm{y}}{\mathrm{y}^{\top} \mathrm{y}} . \tag{A.7}
\end{align*}
$$

Now using Claim A. 6 with $f(t)=t_{1}$ and $\varepsilon=1 / 64$,

$$
\begin{align*}
& \Delta_{1}\left(\boldsymbol{H}_{12}^{\prime}\right)=\max _{\mathrm{v} \leq t_{2}}\left\{d_{t_{2}}^{\prime}(v)\right\} \leq t_{2}^{p / 2+\varepsilon} \leq t^{297 / 1024} \\
& \Delta_{1}\left(\boldsymbol{H}_{23}^{\prime}\right)=\max _{t_{1} \leq v \leq t_{3}}\left\{d_{t_{3}}^{\prime}(v)\right\} \leq t_{3}^{p / 2+\varepsilon} / t_{1}^{p / 2} \leq t^{29 / 64} \tag{A.8}
\end{align*}
$$

Finally, all edges in $\boldsymbol{H}_{13}^{\prime}$ are between $S_{1}$ and $S_{3}^{\prime}$, so Claim A. 7 shows $\Delta_{1}\left(\boldsymbol{H}_{13}^{\prime}\right) \leq t^{p-9 / 16} \leq t^{7 / 16}$ whp. Putting together Equations (A.7) and (A.8), we get $\lambda_{1}\left(\boldsymbol{H}_{i j}\right) \leq m \lambda_{1}\left(\boldsymbol{H}_{i j}^{\prime}\right) \leq m \Delta_{1}\left(\boldsymbol{H}_{i j}^{\prime}\right)^{1 / 2} \leq m t^{15 / 64}$. And so we get the final bound

$$
\lambda_{1}\left(\boldsymbol{A}_{H}\right) \leq \sum_{i=1}^{3} \lambda_{1}\left(\boldsymbol{H}_{i}\right)+\sum_{i<j} \lambda_{1}\left(\boldsymbol{H}_{i j}\right) \leq 6 m t^{15 / 64} .
$$

This shows that $\lambda_{i}\left(\boldsymbol{A}_{H}\right)$ is $o\left(\lambda_{k}\left(\boldsymbol{A}_{F}\right)\right)$, which implies $\lambda_{i}\left(\boldsymbol{A}_{G}\right)=\lambda_{i}\left(\boldsymbol{A}_{G}\right)=\lambda_{i}\left(\boldsymbol{A}_{F}\right)(1 \pm o(1))$. This concludes the final claim.

And this concludes the proof.

## Appendix B. TGPA spectral power law proofs

In this appendix, we provide proofs for theoretical results from Section 6.
Proof of Lemma 6.1. Denote $G_{t}^{m}$ as the graph at time $t$ with contractions of size $m$. Let $Z_{t}=d_{t}^{m}(s)$ be the degree of vertex $s$ at time $t$. Let $Y_{t}$ be an indicator for the event that only one edge added at time $t$ is incident to $s$, and let $X_{t}$ be an indicator variable for the event that both of the edges added at time $t$ are incident to $s$. First, let us calculate the probability of placing exactly one edge incident to node $s$ at time $t$ :

$$
\begin{aligned}
& p\left[\frac{d_{t}(s)}{4 t-2}\left(1-\frac{2(\text { num of self-loops })}{d_{t}(s)}\right)+\frac{\sum_{u \in N(s), u \neq s} d_{t}(u)}{4 t-2}\left(\frac{\text { num edges btwn u, st }}{\substack{\text { probility of picking s first, and then not picking it } \\
\text { second }}}\right)\right] \\
& =p\left[\frac{d_{t}(s)}{2 t-1}-\frac{2(\text { num self-loops })}{2 t-1}\right] .
\end{aligned}
$$

Also the probability of placing two (both) edges incident to node $s$ at time $t$ :

$$
p \frac{d_{t}(s)}{4 t-2} \cdot \operatorname{Pr}[\text { picking it second } \mid \text { picked it first }]=\frac{d_{t}(s)}{4 t-2} \cdot \frac{2(\text { num self-loops })}{d_{t}(s)}=\frac{\text { num self-loops }}{2 t-1} .
$$

Then, we can write the expectation of $Z_{t}$ in terms of $Z_{t-1}$ using the above calculations:

$$
\begin{aligned}
& \mathbb{E}\left[Z_{t}^{\bar{k})}\right]=\mathbb{E}\left[\mathbb{E}\left[\left(Z_{t-1}+Y_{t}+2 X_{t}\right)^{(\bar{k})}\right] \mid Z_{t-1}\right] \\
& =\mathbb{E}\left[\left(Z_{t-1}+2\right)^{(\bar{k})} p \cdot\left(\frac{\text { num self-loops }}{2 t-1}\right)+\left(Z_{t-1}+1\right)^{(\bar{k})} p \cdot\left(\frac{d_{t}(s)}{2 t-1}-\frac{2 \text { (num self-loops) }}{2 t-1}\right)\right. \\
& \left.+Z_{t-1}^{(\bar{k})}\left(1-p \frac{d_{t}(s)}{2 t-1}+p \frac{\text { num self-loops }}{2 t-1}\right)\right] \\
& \leq \mathbb{E}\left[\left(Z_{t-1}+2\right)^{(\bar{k})} p \cdot\left(\frac{\text { num self-loops }}{2 t-1}\right)+\left(Z_{t-1}+2\right)^{(\bar{k})} p \cdot\left(\frac{d_{t}(s)}{2 t-1}-\frac{2 \text { (num self-loops) }}{2 t-1}\right)\right.
\end{aligned}
$$

$$
\begin{aligned}
&\left.\quad+Z_{t-1}^{(\bar{k})}\left(1-p \frac{d_{t}(s)}{2 t-1}+p \frac{\text { num self-loops }}{2 t-1}\right)\right] \\
&= \mathbb{E}\left[\left(Z_{t-1}+2\right)^{(\bar{k})} p \cdot\left(\frac{d_{t}(s)}{2 t-1}-\frac{\text { num self-loops }}{2 t-1}\right)+Z_{t-1}^{(\bar{k})}\left(1-p \frac{d_{t}(s)}{2 t-1}+p \frac{\text { num self-loops }}{2 t-1}\right)\right] \\
&=\mathbb{E}\left[Z_{t-1}^{(\bar{k})}\left(1-p \frac{Z_{t-1}}{2 t-1}+p \frac{\text { num self-loops }}{2 t-1}+\frac{Z_{t-1}+k}{Z_{t-1}}\left(p \frac{Z_{t-1}}{2 t-1}-p \frac{\text { num self-loops }}{2 t-1}\right)\right)\right] \\
&=\mathbb{E}\left[Z_{t-1}^{(\bar{k})}\left(1-p \frac{Z_{t-1}-\text { num self-loops }}{2 t-1}+\frac{Z_{t-1}+k}{Z_{t-1}}\left(p \frac{Z_{t-1}-\text { num self-loops }}{2 t-1}\right)\right)\right] \\
& \leq \mathbb{E}\left[Z_{t-1}^{(\bar{k})}\left(1-p \frac{Z_{t-1}-\text { num self-loops }}{2 t-1}+p \frac{Z_{t-1}+k}{2 t-1}\right)\right] \\
&=\mathbb{E}\left[Z_{t-1}^{(\bar{k})}\left(1+\frac{p}{2 t-1}(k+\text { num self-loops })\right)\right] .
\end{aligned}
$$

Now if $k \geq$ number self-loops we can move on to:

$$
\begin{equation*}
\mathbb{E}\left[Z_{t}^{(\bar{k})}\right] \leq \mathbb{E}\left[Z_{t-1}^{(\bar{k})}\left(1+\frac{2 p k}{2 t-1}\right) .\right] \tag{B.1}
\end{equation*}
$$

Apply this relationship iteratively, down to the time when node $s$ was added (recall we denoted that time as $s^{\prime}$ ). Also note that the degree of $s$ at time $s^{\prime}$ is bounded by $4 m$ (if all m edges were added as self-loops). Thus:

$$
\begin{equation*}
\mathbb{E}\left(Z_{t}^{(\bar{k})}\right)=\prod_{t^{\prime}=s^{\prime}}^{t}\left(1+\frac{2 p k}{2 t^{\prime}-1}\right) \leq(4 m)^{(\bar{k})} \prod_{t^{\prime}=s^{\prime}+1}^{t}\left(1+\frac{2 p k}{2 t^{\prime}-1}\right) . \tag{B.2}
\end{equation*}
$$

Use $1+x \leq e^{x}$ to write the product as a sum, and bound the sum with an integral:

$$
\begin{equation*}
\sum_{t^{\prime}=s^{\prime}+1}^{t} \frac{1}{t^{\prime}-1 / 2} \leq \int_{x=s^{\prime}}^{t} \frac{1}{x-1 / 2} \mathrm{dx}=\log \frac{t-1 / 2}{s^{\prime}-1 / 2} \tag{B.3}
\end{equation*}
$$

So finally,

$$
\begin{align*}
\mathbb{E}\left(Z_{t}^{(\bar{k})}\right) & \leq(4 m)^{(\bar{k})}\left(\frac{t-1 / 2}{s^{\prime}-1 / 2}\right)^{p k} \\
& =(4 m)^{(\bar{k})}\left(\frac{t}{s^{\prime}}\right)^{p k / 2}\left(\frac{2-1 / t}{2-1 / s^{\prime}}\right)^{p k}  \tag{B.4}\\
& \leq(4 m)^{(\bar{k})}\left(\frac{t}{s^{\prime}}\right)^{p k} 2^{p k} .
\end{align*}
$$

Proof of Lemma 6.2. Let $\tau^{(i)}=\left(\tau_{1}^{(i)}, \ldots, \tau_{r_{i}}^{(i)}\right)$, where $\tau_{j}^{(i)}$ is the time when we add an edge incident to $S_{i}$ and increase the degree of $S_{i}$ from $d_{i}+j-1$ to $d_{i}+j$. Note that we could have repeated times in $\tau^{(i)}$. Define $\tau=\left(\tau_{0}, \tau_{1}, \ldots, \tau_{r+1}\right)$ to be the ordered union of $\tau^{(i)}$, with $\tau_{0}=t_{0}$ and $\tau_{r+1}=t$. Again, there may be up to two moves per time step. Let $p\left(\tau ; \mathrm{d}, t_{0}, t\right)$ be the probability that supernodes $S_{i}$ increase in degree at exactly the times specified by $\tau$ between time $t_{0}$ and $t$. Define all time steps to be $T:=\left\{t_{0}, t_{1}, t_{1}, t_{2}, t_{2}, \ldots, t_{r}, t_{r}\right\}$. Time steps involving the sets $S_{i}$ we defined to be $\tau$. So the remaining time steps are $T-\tau$. Then

$$
\begin{align*}
& \text { for each time step in between the relevant ones, } \\
& \text { the probability of picking any edge outside of }  \tag{B.5}\\
& S_{1}, \ldots, S_{l} \text {. } \\
& =\left(\prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!}\right)\left(\prod_{k=1}^{r} \frac{p}{2 \tau_{k}-1}\right) \exp \left\{\sum_{\substack { k=0 \\
\begin{subarray}{c}{j \in T-\tau \\
j \geq \tau_{k} \\
j<\tau_{k+1}{ k = 0 \\
\begin{subarray} { c } { j \in T - \tau \\
j \geq \tau _ { k } \\
j < \tau _ { k + 1 } } }\end{subarray}} \log \left(1-p\left(\frac{d+k}{2 j-1}\right)\right)\right\} .
\end{align*}
$$

Now we can bound the inner most sum of the exponential term as

$$
\begin{equation*}
\sum_{\substack{j \in T-\tau \\ j \geq \tau_{k} \\ j<\tau_{k+1}}} \log \left(1-p\left(\frac{d+k}{2 j-1}\right)\right) \leq 2 \sum_{j=\tau_{k}+1}^{\tau_{k+1}-1} \log \left(1-\frac{p(d+k)}{2 j}\right), \tag{B.6}
\end{equation*}
$$

which is less than or equal to

$$
\begin{align*}
2 \int_{\tau_{k}+1}^{\tau_{k+1}} \log \left(1-\frac{p(d+k)}{2 x}\right) \mathrm{dx}= & -2 \tau_{k+1} \log \left(2 \tau_{k+1}\right)+2\left(\tau_{k}+1\right) \log \left(2 \tau_{k}+2\right) \\
& +\left(2 \tau_{k+1}-p(d+k)\right) \log \left(2 \tau_{k+1}-p(d+k)\right)  \tag{B.7}\\
& -\left(2 \tau_{k}+2-p(d+k)\right) \log \left(2 \tau_{k}+2-p(d+k)\right) .
\end{align*}
$$

Note that $\tau_{0}=t_{0}$ and $\tau_{r+1}=t$. Then we can write

$$
\begin{equation*}
\sum_{k=0}^{r} \int_{\tau_{k}+1}^{\tau_{k+1}} \log \left(1-\frac{p(d+k)}{2 x}\right) \mathrm{dx}=A+\sum_{k=1}^{r} B_{k} \tag{B.8}
\end{equation*}
$$

where

$$
\begin{align*}
A= & 2\left(t_{0}+1\right) \log \left(2 t_{0}+2\right)-\left(2 t_{0}+2-p d\right) \log \left(2 t_{0}+2-p d\right) \\
& -2 t \log (2 t)+(2 t-p(d+r)) \log (2 t-p(d+r)) \tag{B.9}
\end{align*}
$$

and

$$
\begin{align*}
B_{k}= & 2 \tau_{k} \log \left(1+1 / \tau_{k}\right)+2 \log \left(2 \tau_{k}+2\right)-(2-p) \log \left(2 \tau_{k}+p-p(d+k)\right) \\
& +\left(2 \tau_{k}+2-p(d+k)\right) \log \left(1-\frac{2-p}{2 \tau_{k}+2-p(d+k)}\right) \tag{B.10}
\end{align*}
$$

We will bound each of $A$ and $B_{k}$, starting with $B_{k}$. Since $1+x \leq e^{x}, 1 \tau_{k} \log \left(1+1 / \tau_{k}\right) \leq 2$ and $\left(2 \tau_{k}+2-p(d+k)\right) \log \left(1-\frac{2-p}{2 \tau_{k}+2-p(d+k)}\right) \leq p-2$. Rearranging the other two terms of Equation (B.10) and combining with these inequalities we get

$$
\begin{equation*}
B_{k} \leq p \log \left(2 \tau_{k}+2\right)-(2-p) \log \left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)+p \tag{B.11}
\end{equation*}
$$

Now rearranging terms of $A$ from Equation (B.9),

$$
\begin{align*}
A= & -2\left(t_{0}+1\right) \log \left(1-\frac{p d}{2 t_{0}+2}\right)+p d \log \left(2 t_{0}+2-p d\right) \\
& +2 t \log \left(1-\frac{p(d+r)}{2 t}\right)-p(d+r) \log (2 t-p(d+r)) \\
e^{A}= & \left(1-\frac{p d}{2 t_{0}+2}\right)^{-2\left(t_{0}+1\right)}\left(2 t_{0}+2-p d\right)^{p d}\left(1-\frac{p(d+r)}{2 t}\right)^{2 t}(2 t-p(d+r))^{-p(d+r)}  \tag{B.12}\\
= & \left(1-\frac{p d}{2 t_{0}+2}\right)^{-2\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)\left(t_{0}+1\right)}\left(1-\frac{p(d+r)}{2 t}\right)^{2 t-p(d+r)}\left(\frac{t_{0}+1}{t}\right)^{p d}(2 t)^{-p r} .
\end{align*}
$$

Using the bound $1-x \leq e^{-x-x^{2} / 2}$ for $0<x<1$,

$$
\begin{equation*}
\left(1-\frac{p(d+r)}{2 t}\right)^{2 t-p(d+r)} \leq \exp \left\{-p(d+r)+\frac{p^{2}(d+r)^{2}}{4 t}+\frac{p^{3}(d+r)^{3}}{8 t^{2}}\right\} \tag{B.13}
\end{equation*}
$$

Putting the bounds on $A$ and $B_{k}$ together, we get

$$
\begin{gather*}
e^{A+\sum B_{k}} \leq\left(1-\frac{p d}{2 t_{0}+2}\right)^{-2\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)\left(t_{0}+1\right)} \exp \left\{-p(d+r)+\frac{p^{2}(d+r)^{2}}{4 t}+\frac{p^{3}(d+r)^{3}}{8 t^{2}}\right\}  \tag{B.14}\\
\times\left(\frac{t_{0}+1}{t}\right)^{p d}(2 t)^{-p r} \prod_{k=1}^{r}\left(\left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)^{-(2-p)}\left(2 \tau_{k}+2\right)^{p}\right) e^{p r} .
\end{gather*}
$$

Using

$$
\begin{equation*}
\operatorname{err}\left(r, d, t_{0}, t\right)=\left(1-\frac{p d}{2 t_{0}+2}\right)^{-2\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)\left(t_{0}+1\right)} \exp \left\{-p d+\frac{p^{2}(d+r)^{2}}{4 t}+\frac{p^{3}(d+r)^{3}}{8 t^{2}}\right\} \tag{B.15}
\end{equation*}
$$

we can write Equation (B.14) as

$$
\begin{equation*}
e^{A+\sum B_{k}} \leq \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d}(2 t)^{-p r} \prod_{k=1}^{r}\left(\left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)^{-(2-p)}\left(2 \tau_{k}+2\right)^{p}\right) . \tag{B.16}
\end{equation*}
$$

So, we finally finish with the bound on $p\left(\tau ; \mathrm{d}, t_{0}, t\right)$ by substituting Equation (B.16) into Equation (B.5):

$$
\begin{align*}
p\left(\tau ; \mathrm{d}, t_{0}, t\right) \leq & \left(\prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!}\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d}(2 t)^{-p r} \\
& \times \prod_{k=1}^{r}\left(\left(1-\frac{p(d+k)+2-p}{2 \tau_{k}+2}\right)^{-(2-p)}\left(2 \tau_{k}+2\right)^{p} \frac{p}{2 \tau_{k}-1}\right) \tag{B.17}
\end{align*}
$$

which can be rearranged as

$$
\begin{align*}
= & \left(\prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!}\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d}(2 t)^{-p r}  \tag{B.18}\\
& \times \prod_{k=1}^{r}\left(p\left(2 \tau_{k}+p-p(d+k)\right)^{-(2-p)}\left(2 \tau_{k}+5+\frac{9}{2 \tau_{k}-1}\right)\right) .
\end{align*}
$$

Now we will sum $p\left(\tau ; \mathrm{d}, t_{0}, t\right)$ over all ordered choices of $\tau$ :

$$
\begin{align*}
p\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right) \leq & \sum_{\tau^{(1)}, \ldots, \tau^{(l)}} p\left(\tau ; \mathrm{d}, t_{0}, t\right) \\
\leq & \binom{r}{r_{1}, \ldots, r_{l}} \sum_{t_{0}+1 \leq \tau_{1}<\ldots<\tau_{r} \leq t} \prod_{i=1}^{l} \frac{\left(r_{i}+d_{i}-1\right)!}{\left(d_{i}-1\right)!} \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d} \\
& \quad \times(2 t)^{-p r} p \prod_{k=1}^{r}\left(2 \tau_{k}+p-p(d+k)\right)^{-(2-p)}\left(2 \tau_{k}+5+\frac{9}{2 \tau_{k}-1}\right)  \tag{B.19}\\
= & r!\left(\prod_{i=1}^{l}\binom{r_{i}+d_{i}-1}{d_{i}-1}\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d}(2 t)^{-p r} \\
& \quad \times \sum_{t_{0}+1 \leq \tau_{1}<\ldots<\tau_{r} \leq t} p \prod_{k=1}^{r}\left(2 \tau_{k}+p-p(d+k)\right)^{-(2-p)}\left(2 \tau_{k}+5+\frac{9}{2 \tau_{k}-1}\right) .
\end{align*}
$$

Now let $\tau_{k}^{\prime}=\tau_{k}-\lceil p(d+k) / 2\rceil$. Since $d \geq 1$ and $k \geq 1$, we have $2\lceil p(d+k) / 2\rceil \geq 2$. Then the last term in Equation (B.19) is less than or equal to

$$
\sum_{\left(t_{0}-p[d / 2\rceil+1\right) \leq \tau_{1}^{\prime} \leq \ldots \leq \tau_{r}^{\prime} \leq(t-p\lceil[(d+r) / 2])}\left(p \prod_{k=1}^{r}\left(2 \tau_{k}^{\prime}+p\right)^{-(2-p)}\left(2 \tau_{k}^{\prime}+5+\frac{9}{2 \tau_{k}^{\prime}+1}\right)\right)
$$

$$
\begin{align*}
& \leq \frac{p}{r!}\left(\sum_{\tau^{\prime}=\left(t_{0}-p[d / 2\rceil+1\right)}^{t-p\lceil(d+r) / 2\rceil}\left(9\left(2 \tau^{\prime}+p\right)^{-(3-p)}+\left(2 \tau_{k}^{\prime}+5\right)\left(2 \tau_{k}^{\prime}+p\right)^{-(2-p)}\right)\right)^{r} \\
& \leq \frac{p}{r!}\left(\int_{0}^{t-p(d+r) / 2}\left(9(2 x+p)^{-(3-p)}+\left(2 \tau_{k}^{\prime}+5\right)(2 x+1)^{-(2-p)}\right) \mathrm{dx}\right)^{r} \\
& \leq \frac{p}{r!}\left(\frac{9}{2(2-p) p^{2-p}}+\frac{5}{(1-p) p^{1-p}}+\frac{2}{(1-p) p}(2 t-p(d+r)+1)^{p}\right)^{r}  \tag{B.20}\\
& \leq \frac{2 p}{r!(1-p) p^{2-p}}\left(\frac{19}{4}+(2 t-p(d+r)+p)^{p}\right)^{r} \\
& =\frac{2}{r!(1-p) p^{1-p}}\left((2 t)^{p}\left(1-\frac{p(d+r)-p}{2 t}\right)^{p}\right. \\
& \leq=\frac{2}{r!(1-p) p^{1-p}}(2 t)^{p r} \underbrace{\left(1-\frac{p(d+r)-p}{2 t}\right)^{p r}}_{\leq \exp \left\{-\frac{-p r(p(d+r)-p)}{2 t}\right\}} \underbrace{\left.\left(1+\frac{19 p}{4(2 t-p(d+r)+p)^{p}}\right)\right)^{p}}_{\leq \exp \left\{\frac{19 p r}{4(2 t-p(d+r)+p)^{p}}\right\}})^{r}
\end{align*}
$$

where the last inequalities come from $1+x \leq e^{x}$. So finally,

$$
\begin{aligned}
p_{S}\left(\mathrm{r} ; \mathrm{d}, t_{0}, t\right) & \leq\left(\prod_{i=1}^{l}\binom{r_{i}+d_{i}-1}{d_{i}-1}\right) \operatorname{err}\left(r, d, t_{0}, t\right)\left(\frac{t_{0}+1}{t}\right)^{p d} \\
& \times \exp \left\{\frac{-p r((d+r)-p)}{2 t}+\frac{19 p r}{4(2 t-p(d+r)+p)^{p}}\right\} .
\end{aligned}
$$

Since $d=o\left(t^{1 / 2}\right)$ and $r=o\left(t^{2 / 3}\right)$,

$$
\begin{aligned}
& \operatorname{err}\left(r, d, t_{0}, t\right) \exp \left\{\frac{-r p((d+r)-p)}{2 t}+\frac{19 p r}{4(2 t-p(d+r)+p)^{p}}\right\} \\
& \leq\left(1-\frac{p d}{2\left(t_{0}+1\right)}\right)^{-2\left(1-p d / 2\left(t_{0}+1\right)\right)\left(t_{0}+1\right)} \exp \left\{1-p d-\frac{r^{2}}{4 t}+\frac{19 p r}{4 t^{p}}\right\} \\
& \leq \begin{array}{c}
\text { since } x^{-x} \leq e
\end{array} e^{2\left(t_{0}+1\right)} \quad \exp \left\{1-p d+\frac{19 p r}{4 t^{p}}\right\} \\
& =\exp \left\{3+2 t_{0}-p d+\frac{19 p r}{4 t^{p}}\right\}
\end{aligned}
$$

This concludes the proof.
Proof of Theorem 6.1. Partition the vertices into those added before time $t_{0}$, before time $t_{1}$ and after $t_{1}$, with $t_{0}=\log \log \log f(t), t_{1}=\log \log f(t)$. We will argue about the maximum degree vertices in each set.

Claim B. 1 In $G_{t}^{m}$, the degree of the supernode of vertices added before time $t_{0}$ is at least $t_{0}^{(1-p) / 2} t^{p}$ whp.

Proof. Consider all vertices added before time $t_{0}$ as a supernode. Let $A_{1}$ denote the event that this supernode has degree less than $t_{0}^{(1-p) / 2} t^{p}$ at time $t$. We will use Lemma 6.2 with $l=1$, and $d=4 t_{0}$ (because the supernode has all edges at time $t_{0}$ ). Calculate $\operatorname{Pr}\left[A_{1}\right]$ as

$$
\begin{aligned}
& \operatorname{Pr}\left[A_{1}\right] \leq \sum_{r_{1}=0}^{t_{0}^{(1-p) / 2} t^{p}-4 t_{0}}\binom{r_{1}+4 t_{0}-1}{4 t_{0}-1}\left(\frac{t_{0}+1}{t}\right)^{p d} e^{3+2 t_{0}-p d+19 p r / 4 t^{p}}
\end{aligned}
$$

$$
\begin{align*}
& =\left(t_{0}^{(1-p) / 2} t^{p}-4 t_{0}\right) \frac{\left(t_{0}^{(1-p) / 2} t^{p}-1\right)!}{\left(4 t_{0}-1\right)!\left(t_{0}^{(1-p) / 2} t^{p}-4 t_{0}\right)!}\left(\frac{t_{0}+1}{t}\right)^{4 p t_{0}} e^{3+2 t_{0}(1-2 p)+(19 / 4) p t_{0}^{1 / 3}-\frac{19 p t_{0}}{t^{p}}}  \tag{B.21}\\
& \leq t_{0}^{(1-p) / 2} t^{p} \frac{\left(t_{0}^{(1-p) / 2} t^{p}\right)^{4 t_{0}-1}}{\left(4 t_{0}-1\right)!}\left(\frac{t_{0}+1}{t}\right)^{4 p t_{0}} e^{3+2 t_{0}(1-2 p)+(19 / 4) p t_{0}^{1 / 3}-19 p t_{0} / t^{p}} \\
& \leq t_{0}^{2(1-p) t_{0}} \frac{e^{4 t_{0}-1}}{\underset{\text { since } 1 / x!\leq e^{x}-1 / x^{x}}{4 t_{0}-1}}\left(t_{0}+1\right)^{4 p t_{0}} e^{3+2 t_{0}(1-2 p)+(19 / 4) p t_{0}^{1 / 3}-19 p t_{0} / t^{p}} \\
& \leq \frac{e^{2+2 t_{0}(3-2 p)+(19 / 4) p t_{0}^{1 / 3}-19 p t_{0} / t^{p}}}{\left(4 t_{0}-1\right)^{2 t_{0}(1-p)-1}},
\end{align*}
$$

which goes to 0 as $t$ goes to infinity. Thus $A_{1}$ does not hold with high probability, and the claim is proved.
Claim B. 2 In $G_{t}^{m}$, no vertex added after time $t_{1}$ has degree exceeding $t_{0}^{-2} t^{p}$ whp.
Proof. Let $A_{2}$ denote the event that some vertex added after time $t_{1}$ has degree exceeding $t_{0}^{-2} t^{p}$. Bound $\operatorname{Pr}\left[A_{2}\right]$ as

$$
\begin{align*}
\operatorname{Pr}\left[A_{2}\right] & \leq \sum_{s=t_{1}}^{t} \operatorname{Pr}\left[d_{t}(s) \geq t_{0}^{-2} t^{p}\right]=\sum_{s=t_{1}}^{t} \operatorname{Pr}\left[\left(d_{t}(s)\right)^{(\bar{l})} \geq\left(t_{0}^{-2} t^{p}\right)^{(\bar{l}]}\right] \leq \sum_{s=t_{1}}^{t} t_{0}^{2 l} t^{-l p} \mathbb{E}\left[\left(d_{t}(s)\right)^{(\bar{l})}\right] \\
& =\sum_{s=t_{1}}^{t} t_{0}^{2 l} t^{-l p}(4 m)^{\text {by Markov }}{ }^{\bar{l})} 2^{l p}\left(\frac{t}{s}\right)^{l p}=2^{l p}(4 m)^{(\bar{l})} t_{0}^{2 l} \int_{t_{1}-1}^{t} x^{-l p} \mathrm{dx}, \tag{B.22}
\end{align*}
$$

and compute the integral in Equation (B.22),

$$
\begin{equation*}
\int_{t_{1}-1}^{t} x^{-l p} \mathrm{dx}=\left.\frac{x^{-l p+1}}{-l p+1}\right|_{t_{1}-1} ^{t}=(-l p+1)^{-1}\left(t^{-l p+1}-\left(t_{1}-1\right)^{-l p+1}\right) \tag{B.23}
\end{equation*}
$$

We want to choose $l$ so that $-l p+1$ is less than 0 . So choose $l>1 / p$. Then the integral in Equation (B.23) is less than or equal to $(l p-1)^{-1}\left(t_{1}-1\right)^{-l p+1}$, and plugging in the computation from Equation (B.23)
into Equation (B.22),

$$
\begin{equation*}
\operatorname{Pr}\left[A_{2}\right] \leq \frac{2^{l p}(4 m)^{(\bar{l}} t_{0}^{2 l}}{(l p-1)\left(t_{1}-1\right)^{l p-1}}, \tag{B.24}
\end{equation*}
$$

which goes to 0 as $t$ increases.
Claim B. 3 In $G_{t}^{m}$, no vertex added before time $t_{1}$ has degree exceeding $t_{0}^{(1-p) / 4} t^{p}$ whp.
Proof. Let $A_{3}$ denote the event that some vertex added before time $t_{1}$ has degree exceeding $t_{0}^{(1-p) / 4} t^{p}$. Using the exact argument as in Claim B.2, $\operatorname{Pr}\left[A_{3}\right]$ goes to 0 as $t$ increases.

Claim B. 4 The k highest degree vertices of $G_{t}^{m}$ are added before time $t_{1}$ and have degree $\Delta_{i}$ bounded by $t_{0}^{-1} t^{p} \leq \Delta_{i} \leq t_{0}^{(1-p) / 4} t^{p}$.

Proof. First lets summarize the results of the last three claims:

- Bound on degrees of vertices added after time $t_{1}: t_{0}^{-2} t^{p}$
- Bound on degrees of vertices added before time $t_{1}: t_{0}^{(1-p) / 4} t^{p}$
- Sum of all degrees added before time $t_{0}$ is at least: $t_{0}^{(1-p) / 2} t^{p}$

So the upper bound of the claim is immediately clear from the second item. Suppose that the lower bound does not hold. Then one of the top $k$ vertices has degree less than $t_{0}^{-1} t^{p}$ and the total degree of vertices added before time $t_{0}$ is bounded by

$$
\begin{align*}
& \underbrace{(k-1) t_{0}^{(1-p) / 4} t^{p}}_{\substack{\text { largest possible degrees of }(k-1) \\
\text { vertices }}}+\underbrace{\left(\frac{t_{0}}{m}-k+1\right)\left(t_{0}^{-1} t^{p}\right)}_{\substack{\text { largest possible degrees of } \\
\text { remaining veritices }}} \leq k t_{0}^{(1-p) / 4} t^{p}+t_{0}\left(t_{0}^{-1} t^{p}\right)  \tag{B.25}\\
& =k t_{0}^{(1-p) / 4} t^{p}+t^{p}=t^{p}\left(k t_{0}^{(1-p) / 4}+1\right) \leq t^{p}\left(2 k t_{0}^{(1-p) / 4}\right) \leq t^{p} t_{0}^{(1-p) / 2},
\end{align*}
$$

which contradicts the third bulleted item. Finally, since we have the lower bound, and we know that $t^{p} / t_{0} \geq t^{p} / t_{0}^{2}$, then none of the largest degree vertices could be added after time $t_{1}$.

Claim B. 5 The $k$ highest degree vertices of $G_{t}^{m}$ have $\Delta_{i} \leq \Delta_{i-1}-\frac{t^{p}}{f(t)}$ whp.
Proof. Let $A_{4}$ denote the event that there are two vertices among the first $t_{1}$ time steps with degrees exceeding $t_{0}^{-1} t^{p}$ and within $t^{p} / f(t)$ of each other. Define

$$
p_{l, s_{1}, s_{2}}=\operatorname{Pr}\left[d_{t}\left(s_{1}\right)-d_{t}\left(s_{2}\right)=l \mid \bar{A}_{3}\right], \text { for }|l| \leq t^{p} / f(t)
$$

where $\bar{A}_{3}$ is defined to be the opposite of event $A_{3}$ from Claim B.3. Then

$$
\begin{equation*}
\operatorname{Pr}\left[A_{4} \mid \bar{A}_{3}\right] \leq \sum_{1 \leq s_{1}<s_{2} \leq t_{1}} \sum_{l=-t^{p} / f(t)}^{t^{p} / f(t)} p_{l, s_{1}, s_{2}} . \tag{B.26}
\end{equation*}
$$

Now

$$
\begin{equation*}
p_{l, s_{1}, s_{2}} \leq \sum_{r_{1}=t_{0}^{-1} t t^{p}}^{t_{0}^{(1-p) / 4_{1} p}} \sum_{d_{1}, d_{2}=1}^{4 t_{1}} p_{\substack{\left.s_{1}, s_{2}\right) \\ \text { Notation from Lemma } 6.2}}\left(\left(r_{1}, r_{1}-l\right) ;\left(d_{1}, d_{2}\right), t_{1}, t\right) \tag{B.27}
\end{equation*}
$$

Using Lemma 6.2,

$$
\begin{gather*}
\leq \sum_{r_{1} t_{0}^{-1} t^{p}} \sum_{d_{1}, d_{2}=1}^{t_{0}^{(1-p) / 4} t^{p}}\binom{r_{1}+d_{1}-1}{d_{1}-1}\binom{r_{1}-l+d_{2}-1}{d_{2}-1}\left(\frac{t_{1}+1}{t}\right)^{p\left(d_{1}+d_{2}\right)}  \tag{B.28}\\
\times e^{\left\{3+2 t_{1}-p\left(d_{1}+d_{2}\right)+\frac{19 p\left(r_{1}-l\right)}{4 p^{p}}\right\}} \\
\leq t_{0}^{(1-p) / 4} t^{p} \sum_{d_{1}, d_{2}=1}^{4 t_{1}}\binom{t_{0}^{(1-p) / 4} t^{p}+d_{1}-1}{d_{1}-1}\binom{t_{0}^{(1-p) / 4} t^{p}-l+d_{2}-1}{d_{2}-1}\left(\frac{t_{1}+1}{t}\right)^{p\left(d_{1}+d_{2}\right)} \\
\leq\left\{\begin{array}{c}
3+2 t_{1}-p\left(d_{1}+d_{2}\right)+\frac{19 p t_{0}^{(1-p) / 4} t^{p}}{4 p^{p}}
\end{array}\right\} \\
\leq t_{0}^{(1-p) / 4} t^{p} \sum_{d_{1}, d_{2}=1}^{4 t_{1}}\binom{2 t_{0}^{(1-p) / 4} t^{p}}{d_{1}-1}\binom{2 t_{0}^{(1-p) / 4} t^{p}}{d_{2}-1}\left(\frac{t_{1}+1}{t}\right)^{p\left(d_{1}+d_{2}\right)}  \tag{B.29}\\
\times e^{3+2 t_{1}+(19 / 4) p t_{0}^{(1-p) / 4}} \\
\leq t_{0}^{(1-p) / 4} t^{p} \sum_{d_{1}, d_{2}=1}^{4 t_{1}}\left(2 t_{0}^{(1-p) / 4} t^{p}\right)^{d_{1}+d_{2}-2}\left(t_{1}+1\right)^{8 p t_{1}} t^{-p\left(d_{1}+d_{2}\right)} e^{3+2 t_{1}+(19 / 4) p t_{0}^{(1-p) / 4}} \\
=t^{-p} t_{0}^{(1-p) / 4}\left(4 t_{1}\right)^{2} 2^{8 t_{1}} t_{0}^{2 t_{1}(1-p)}\left(t_{1}+1\right)^{8 p t_{1}} e^{3+2 t_{1}+(19 / 4) p t_{0}^{(1-p) / 4}} .
\end{gather*}
$$

Denote the last equation as $h(t)$ and note $h(t)$ is a polynomial in $\log (f(t))$ times a factor of $t^{-p}$. Then going back to Equation (B.26),

$$
\begin{equation*}
\operatorname{Pr}\left[A_{4} \mid \bar{A}_{3}\right] \leq\binom{ t_{1}}{2} 2 \frac{t^{p}}{f(t)} h(t)=\binom{t_{1}}{2} 2 \frac{\operatorname{poly}(\log (f(t)))}{f(t)} \tag{B.30}
\end{equation*}
$$

which goes to 0 as $t$ increases. This concludes the proof of this final claim.
And this concludes the proof of the theorem.
Proof of Theorem 6.2. Let $S_{i}$ be the vertices added after time $t_{i-1}$ and at or before time $t_{i}$, for $t_{0}=0, t_{1}=$ $t^{1 / 8}, t_{2}=t^{9 / 16}, t_{3}=t$. Let $G=G_{t}$. We start by finding bounds on the degrees and co-degrees of $G$.

Claim B. 6 For any $\varepsilon>0$, and any $f(t)$ with $f(t) \rightarrow \infty$ as $t \rightarrow \infty$ the following holds whp: for all $s$ with $f(t) \leq s \leq t$, for all vertices $v \in G_{s}$, if $v$ was added at time $r$, then $d_{s}(v) \leq s^{p+\varepsilon} r^{-p}$.

## Proof.

$$
\begin{align*}
& \operatorname{Pr}\left[\cup_{s=f(t)}^{t} \cup_{r=1}^{s}\left\{d_{s}^{m}(r) \geq s^{p+\varepsilon} r^{-p}\right\}\right] \leq \sum_{s=f(t)}^{t} \sum_{r=1}^{s} \operatorname{Pr}\left[d_{s}^{m}(r) \geq s^{p+\varepsilon} r^{-p}\right]  \tag{B.31}\\
& =\sum_{s=f(t)}^{t} \sum_{r=1}^{s} \operatorname{Pr}\left[\left(d_{s}^{m}(r)\right)^{\bar{l})} \geq\left(s^{p+\varepsilon} r^{-p}\right)^{\bar{l}}\right]
\end{align*}
$$

which is bounded using Markov:

$$
\leq \sum_{s=f(t)}^{t} \sum_{r=1}^{s} s^{-l(p+\varepsilon)} r^{p l} \mathbb{E}\left[\left(d_{s}^{m}(r)\right)^{(\bar{l})}\right]
$$

We can bound the preceding equation using Lemma 6.1

$$
\leq \sum_{s=f(t)}^{t} \sum_{r=1}^{s} s^{-l(p+\varepsilon)} r^{l p}(4 m)^{\bar{l} \bar{l}} 2^{l p}\left(\frac{s}{r}\right)^{l p}=(4 m)^{(l)} 2^{l p} \sum_{s=f(t)}^{t} s^{1-\varepsilon l}
$$

Take $l \geq 3 / \varepsilon$. Then we can bound the sum by an integral,

$$
\begin{equation*}
\sum_{s=f(t)}^{t} s^{1-\varepsilon l} \leq \int_{f(t)-1}^{\infty} x^{1-\varepsilon l} \mathrm{dx}=\left.\frac{1}{2-\varepsilon l} x^{2-\varepsilon l}\right|_{f(t)-1} ^{\infty}=\frac{1}{\varepsilon l-2}(f(t)-1)^{2-\varepsilon l}, \tag{B.32}
\end{equation*}
$$

which goes to zero as $t$ increases, since $l \geq 3 / \varepsilon$.

Claim B. 7 Let $S_{3}^{\prime}$ be the set of vertices in $S_{3}$ that are adjacent to more than one vertex of $S_{1}$ in $G$. Then $\left|S_{3}^{\prime}\right| \leq t^{2 p-9 / 16}$ with high probability.

Proof. Let $B_{1}$ be the event that the conditions of Claim B. 6 hold with $f(t)=t_{2}$ and $\varepsilon=1 / 16$. Then for a vertex $v \in S_{3}$ added at time $s$, the probability that $v$ picks at least one neighbour in $S_{1}$ is less than or equal to

$$
\begin{equation*}
\frac{2 \sum_{w \in S_{1}} d_{s}(w)}{4 s-2} \leq \frac{\sum_{w \in S_{1}} s^{p+\varepsilon}}{2 s-1}=\frac{t_{1} s^{p+\varepsilon}}{2 s-1} \tag{B.33}
\end{equation*}
$$

So, the probability of having two or more neighbours in $S_{1}$ can be bounded by

$$
\begin{equation*}
\operatorname{Pr}\left[\left|N(v) \cap S_{1}\right| \geq 2 \mid B_{1}\right] \leq\left(\frac{t_{1} s^{p+\varepsilon}}{2 s-1}\right)^{2} \cdot\binom{2 m}{2} \leq m^{2} t^{1 / 4} s^{(16 p-15) / 8} \tag{B.34}
\end{equation*}
$$

Let $X$ denote the number of $v \in S_{3}$ adjacent to more than one vertex of $S_{1}$. Then

$$
\begin{align*}
\mathbb{E}\left[X \mid B_{1}\right] & \leq \sum_{t_{2}+1}^{t} m^{2} s^{(-15+16 p) / 8} t^{1 / 4} \leq m^{2} t^{1 / 4} \int_{t_{2}}^{t} x^{(-15+16 p) / 8} \mathrm{dx} \\
& =m^{2} t^{1 / 4}\left[\left.\frac{8}{-7+16 p} x^{(-7+16 p) / 8}\right|_{t_{2}} ^{t}\right] \leq \frac{8 m^{2} t^{1 / 4}}{-7+16 p} t^{(-7+16 p) / 8} . \tag{B.35}
\end{align*}
$$

Then by Markov,

$$
\begin{equation*}
\operatorname{Pr}\left[X \geq t^{2 p-9 / 16} \mid B_{1}\right] \leq \frac{\mathbb{E}\left[X \mid B_{1}\right]}{t^{2 p-9 / 16}} \leq \frac{8 m^{2}}{16 p-7} \frac{t^{2 p-5 / 8}}{t^{2 p-9 / 16}}=\frac{8 m^{2}}{16 p-7} \frac{t^{-5 / 8}}{t^{-9 / 16}}, \tag{B.36}
\end{equation*}
$$

and $\frac{t^{-5 / 8}}{t^{-9 / 16}}=\frac{t^{9 / 16}}{t^{10 / 16}}$ which goes to zero.
Let $F \subseteq G$ be the star forest consisting of edges between $S_{1}$ and $S_{3} \backslash S_{3}^{\prime}$.

CLaim B. 8 Let $\Delta_{1} \geq \Delta_{2} \geq \ldots \geq \Delta_{k}$ denote the degrees of the $k$ highest degree vertices of $G$. Then $\lambda_{i}(F)=(1-o(1)) \Delta_{i}^{1 / 2}$.

Proof. Denote $K_{1, d_{i}}$ to be a star of degree $d_{i}$. Let $H$ be the star forest $H=K_{1, d_{1}} \cup \ldots \cup K_{1, d_{k}}$ with $d_{1} \geq d_{2} \geq \ldots \geq d_{k}$. Then for $i=1, \ldots, k, \lambda_{i}(H)=d_{i}^{1 / 2}$. So, it will be sufficient to show that $\Delta_{i}(F)=(1-o(1)) \Delta_{i}(G)$. Claim B. 4 shows that the $k$ highest degree vertices $G$ are added before time $t_{1}$. So these vertices are all in $F$. The only edges to those vertices that are not in $F$ are those added before time $t_{2}$ and those incident to $S_{3}^{\prime}$.

By Theorem 6.1, we can choose $f(t)$ such that, $\Delta_{1}\left(G_{t_{2}}^{m}\right) \leq t_{2}^{p} f(t) \leq t^{7 p / 16}$. Also by Theorem 6.1, $\Delta_{i}(G) \geq t^{p} / \log t$. Finally, Claim B. 7 says that $\left|S_{3}^{\prime}\right| \leq t^{7 p / 16}$ whp. And so, with high probability,

$$
\begin{align*}
\Delta_{i}(F) & \geq \Delta_{i}(G)-t^{7_{p / 16}}-m t^{7 p / 16} \geq \frac{t^{p}}{\log t}-t^{7_{p / 16}}(1+m)=\frac{t^{p / 2}}{\log t}\left[1-t^{7_{p / 16}}(1+m) \frac{\log t}{t^{p}}\right]  \tag{B.37}\\
& =\frac{t^{p}}{\log t}\left[1-(1+m) \frac{\log t}{t^{p-7 p / 16}}\right]=\frac{t^{p}}{\log t}\left[1-(1+m) \frac{\log t}{t^{9 p / 16}}\right]=(1-o(1)) \Delta_{i}(G)
\end{align*}
$$

Let $H=G \backslash F$. Denote $\boldsymbol{A}_{G}, \boldsymbol{A}_{F}$ and $\boldsymbol{A}_{H}$ to be the adjacency matrices for graphs $G, F$ and $H$. In the following claim, we'll show that $\lambda_{1}\left(\boldsymbol{A}_{H}\right)$ is $o\left(\lambda_{k}\left(\boldsymbol{A}_{F}\right)\right)$. Consider the fact that $\boldsymbol{A}_{F}$ and $\boldsymbol{A}_{F}+\boldsymbol{A}_{H}=\boldsymbol{A}_{G}$ are symmetric matrices, which implies $\lambda_{k}\left(\boldsymbol{A}_{G}\right) \leq \lambda_{k}\left(\boldsymbol{A}_{F}\right)+\lambda_{1}\left(\boldsymbol{A}_{H}\right)$ (see for instance theorem 8.1.5 in [37]). That implies that for any subspace $L$,

$$
\max _{\mathrm{x} \in L, \mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{G} \mathrm{X}}{\mathrm{x}^{\top} \mathrm{X}}=\max _{\mathrm{x} \in L, \mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{F} \mathrm{X}}{\mathrm{x}^{\top} \mathrm{x}} \pm O\left(\max _{\mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{H} \mathrm{X}}{\mathrm{x}^{\top} \mathrm{x}}\right) .
$$

We will use the Courant-Fischer Minimax Theorem, which states

$$
\lambda_{i}(H)=\min _{S} \max _{x \in S, x \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{A}_{H} \mathrm{x}}{\mathrm{x}^{\top} \mathrm{x}},
$$

where $S \subset \mathbb{R}^{i}$ (see, e.g. [37] Theorem 8.1.2). That will be enough to finish the proof with $\lambda_{i}\left(\boldsymbol{A}_{G}\right)=$ $\lambda_{i}\left(\boldsymbol{A}_{F}\right)(1 \pm o(1))$.

Claim B. $9 \lambda_{1}\left(\boldsymbol{A}_{H}\right) \leq 6 m t^{29 / 64} \mathrm{whp}$.
Proof. Let $H_{i}$ denotes the subgraph of $H$ induced by $S_{i}$, and let $H_{i j}$ denotes the subgraph of $H$ containing only edges with one vertex in $S_{i}$ and the other in $S_{j}$. That is, write $\boldsymbol{A}_{H}$ in the following way:

$$
\boldsymbol{A}_{H}=\left[\begin{array}{ccc}
\boldsymbol{H}_{1} & \boldsymbol{H}_{12} & \boldsymbol{H}_{13} \\
\boldsymbol{H}_{21} & \boldsymbol{H}_{2} & \boldsymbol{H}_{23} \\
\boldsymbol{H}_{31} & \boldsymbol{H}_{32} & \boldsymbol{H}_{3}
\end{array}\right] .
$$

We will use this to bound the maximal eigenvalue of $\boldsymbol{A}_{H}$ as

$$
\begin{align*}
\lambda_{1}\left(\boldsymbol{A}_{H}\right) & =\lambda_{1}\left(\left[\begin{array}{ccc}
\boldsymbol{H}_{1} & \boldsymbol{H}_{12} & \boldsymbol{H}_{13} \\
\boldsymbol{H}_{21} & \boldsymbol{H}_{2} & \boldsymbol{H}_{23} \\
\boldsymbol{H}_{31} & \boldsymbol{H}_{32} & \boldsymbol{H}_{3}
\end{array}\right]\right)  \tag{B.38}\\
& \leq \lambda_{1}\left(\boldsymbol{H}_{1}\right)+\lambda_{1}\left(\boldsymbol{H}_{2}\right)+\lambda_{1}\left(\boldsymbol{H}_{3}\right)+\lambda_{1}\left(\boldsymbol{H}_{12}\right)+\lambda_{1}\left(\boldsymbol{H}_{23}\right)+\lambda_{1}\left(\boldsymbol{H}_{13}\right) .
\end{align*}
$$

Note that the maximum eigenvalue of a graph is at most the maximum degree of a graph. By Claim B. 6 with $f(t)=t_{1}$ and $\varepsilon=1 / 64$,

$$
\begin{align*}
& \lambda_{1}\left(\boldsymbol{H}_{1}\right) \leq \Delta_{1}\left(\boldsymbol{H}_{1}\right)=\max _{v \leq t_{1}}\left\{d_{t_{1}}^{m}(v)\right\} \leq t_{1}^{p+\varepsilon} \leq t^{65 / 512}, \\
& \lambda_{1}\left(\boldsymbol{H}_{2}\right) \leq \Delta_{1}\left(\boldsymbol{H}_{2}\right) \leq \max _{t_{1} \leq v \leq t_{2}}\left\{d_{t_{2}}^{m}(v)\right\} \leq t_{2}^{p+\varepsilon} / t_{1}^{p} \leq t^{457 / 1024},  \tag{B.39}\\
& \lambda_{1}\left(\boldsymbol{H}_{3}\right) \leq \Delta_{1}\left(\boldsymbol{H}_{3}\right) \leq \max _{t_{2} \leq v \leq t_{3}}\left\{d_{t_{3}}^{m}(v)\right\} \leq t_{3}^{p+\varepsilon} / t_{2}^{p} \leq t^{29 / 64} .
\end{align*}
$$

To bound $\lambda_{1}\left(\boldsymbol{H}_{i j}\right)$, start with $m=1$. For $i<j$, this implies that each vertex in $S_{j}$ has at most one edge in $\boldsymbol{H}_{i j}$, that is $H_{i j}$ is a star forest. Then we have a bound on $\boldsymbol{H}_{i j}$ by Claim B.8. For $m>1$, let $G^{\prime}$ be one of our generated graphs with $t$ edges and $m=1$. Think now of contracting vertices in $G^{\prime}$ (only the ones added using PA) into a single vertex. We can write $\boldsymbol{A}_{G}$ in terms of $\boldsymbol{A}_{G}^{\prime}: \boldsymbol{A}_{G}=\boldsymbol{C}^{\top} \boldsymbol{A}_{G}^{\prime} \boldsymbol{C}$, where $\boldsymbol{C}$ is a contraction matrix with $t$ rows and the number of columns equal to the number of vertices in $\boldsymbol{A}_{G}$ (at most $t / m$ ). The $i$ th column is equal to 1 at indices $j$ in which $(i, j)$ are identified. Similarly, we can write $\boldsymbol{H}_{i j}$ in terms of $\boldsymbol{H}_{i j}^{\prime}$.

Note that if $\mathrm{y}=\boldsymbol{C} \mathrm{x}$, then $\mathrm{y}^{\top} \mathrm{y}=\mathrm{x}^{\top} \boldsymbol{C}^{\top} \boldsymbol{C} \mathrm{x}$, where $\boldsymbol{C}^{\top} \boldsymbol{C}$ is a diagonal matrix with $1^{\prime} s$ and $m^{\prime}$ s on the diagonal. So $\mathrm{x}^{\top} \mathrm{x} \leq \mathrm{y}^{\top} \mathrm{y} \leq m \mathrm{x}^{\top} \mathrm{x}$. We use this inequality to bound the largest eigenvalue as

$$
\begin{align*}
\lambda_{1}\left(\boldsymbol{H}_{i j}\right) & =\max _{\mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{H}_{i j} \mathrm{x}}{\mathrm{x}^{\top} \mathrm{x}}=\max _{\mathrm{x} \neq 0} \frac{\mathrm{x}^{\top} \boldsymbol{C}^{\top} \boldsymbol{H}_{i j}^{\prime} \boldsymbol{C} \mathrm{x}}{\mathrm{x}^{\top} \mathrm{x}}=\max _{\mathrm{x} \neq 0, \mathrm{y}=\boldsymbol{C} \mathrm{x}} \frac{\mathrm{y}^{\top} \boldsymbol{H}_{i j}^{\prime} \mathrm{y}}{\mathrm{x}^{\top} \mathrm{x}} \\
& =\max _{\mathrm{x} \neq 0, \mathrm{y}=\boldsymbol{\mathrm { x }}} \frac{m \mathrm{y}^{\top} \boldsymbol{H}_{i j}^{\prime} \mathrm{y}}{m \mathrm{x}^{\top} \mathrm{x}} \leq \max _{\mathrm{x} \neq 0, \mathrm{y}=\boldsymbol{C} \mathrm{x}} \frac{m \mathrm{y}^{\top} \boldsymbol{H}_{i j \mathrm{j}}^{\prime} \mathrm{y}}{\mathrm{y}^{\top} \mathrm{y}} . \tag{B.40}
\end{align*}
$$

Now using Claim B. 6 with $f(t)=t_{1}$ and $\varepsilon=1 / 64$,

$$
\begin{align*}
& \Delta_{1}\left(\boldsymbol{H}_{12}^{\prime}\right)=\max _{v \leq t_{2}}\left\{d_{t_{2}}^{\prime}(v)\right\} \leq t_{2}^{p+\varepsilon} \leq t^{37 / 64}, \\
& \Delta_{1}\left(\boldsymbol{H}_{23}^{\prime}\right)=\max _{t_{1} \leq v \leq t_{3}}\left\{d_{t_{3}}^{\prime}(v)\right\} \leq t_{3}^{p+\varepsilon} / t_{1}^{p} \leq t^{29 / 64} \tag{B.41}
\end{align*}
$$

Finally, all edges in $\boldsymbol{H}_{13}^{\prime}$ are between $S_{1}$ and $S_{3}^{\prime}$, so Claim B. 7 shows $\Delta_{1}\left(\boldsymbol{H}_{13}^{\prime}\right) \leq t^{p-9 / 16} \leq t^{7 / 16}$ whp. Putting together Equations (B.40) and (B.41), we get $\lambda_{1}\left(\boldsymbol{H}_{i j}\right) \leq m \lambda_{1}\left(\boldsymbol{H}_{i j}^{\prime}\right) \leq m \Delta_{1}\left(\boldsymbol{H}_{i j}^{\prime}\right)^{1 / 2} \leq m t^{29 / 64}$. And so we get the final bound,

$$
\lambda_{1}\left(\boldsymbol{A}_{H}\right) \leq \sum_{i=1}^{3} \lambda_{1}\left(\boldsymbol{H}_{i}\right)+\sum_{i<j} \lambda_{1}\left(\boldsymbol{H}_{i j}\right) \leq 6 m t^{29 / 64}
$$

This shows that $\lambda_{1}\left(\boldsymbol{A}_{H}\right)$ is $o\left(\lambda_{k}\left(\boldsymbol{A}_{F}\right)\right)$, which implies $\lambda_{i}\left(\boldsymbol{A}_{G}\right)=\lambda_{i}\left(\boldsymbol{A}_{F}\right)(1 \pm o(1))$.
With the completion of the proof of Claim B.9, that finishes the proof.
