

## Newton Raphson

Used to solve  $f(x) = 0$ . If  $f(x)$ ,  $f'(x)$ ,  $f''(x)$  are continuous, then we can use this information to find the solution of  $f(x)$

<http://www.chem.sc.edu/faculty/morgan/resources/acidbase/nrdoc.html>

From the plot

$$m = f'(x_0)$$

$$m = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$$

$$x_1 = x_0 - \frac{f(x_0)}{f'(x_0)}$$

Newton Raphson and Taylor polynomial

We can approximate a continuous function using a Taylor polynomial expansion around  $x_0$

$$f(x) = f(x_0) + f'(x_0)(x_1 - x_0) + \frac{f''(x_0)(x_1 - x_0)^2}{2!} + \dots$$

Newton Raphson approximates  $f(x)$  by using Taylor expansion up to the first two terms

We will build the Newton Raphson method again but using the Taylor expansion

$$f(x_1) = f(x_0) + f'(x_0)(x_1 - x_0), f(x_1) = 0$$

In fact, we could improve Newton-Raphson by using three terms in the Taylor expansion to construct an improved Newton-Raphson method that also uses the second derivative.

This method produces a function:  $x_1 = g(x_0)$ , when  $g(x)$  is quadratic not linear.

E.X.

$$\sin(x) = 1/2, x \text{ is in radians}$$

$$f(x) = \sin(x) - 1/2 = 0, f'(x) = \cos(x)$$

I	X	F(x <sub>k</sub> )	F'(x <sub>k</sub> )	X(k+1)
0	0	-0.5	1	0.5
1	0.5	-0.02	0.8795	0.522
2	0.522	-0.00139	0.8668	0.5235

Exact solution:  $x=0.5235$

This is more precise and faster than the false position method and the bisection method

Order of Convergence

Assume that  $p$  is a solution for  $f(x) = 0$ . Also assume that  $E = p - p_n$  is the approximation error. If two positive constants,  $A$  is not 0 and  $R > 0$  exist such that

$$\lim_{n \rightarrow \infty} \left\{ \frac{|p - p_{n+1}|}{|p - p_n|^R} \right\}$$

$$= \lim_{n \rightarrow \infty} \left\{ \frac{E_{n+1}}{(E_n)^R} \right\}$$

$$= A$$

Then the sequence is said to converge to  $p$  with an order of convergence  $R$ . This means,

$$|E_{n+1}| = A \cdot |E_n|^R$$

$R$  will tell us how fast a method converges

$R=1$ : convergence is linear

$R=2$ : convergence is quadratic

usually the more roots a question has, the slower the convergence is

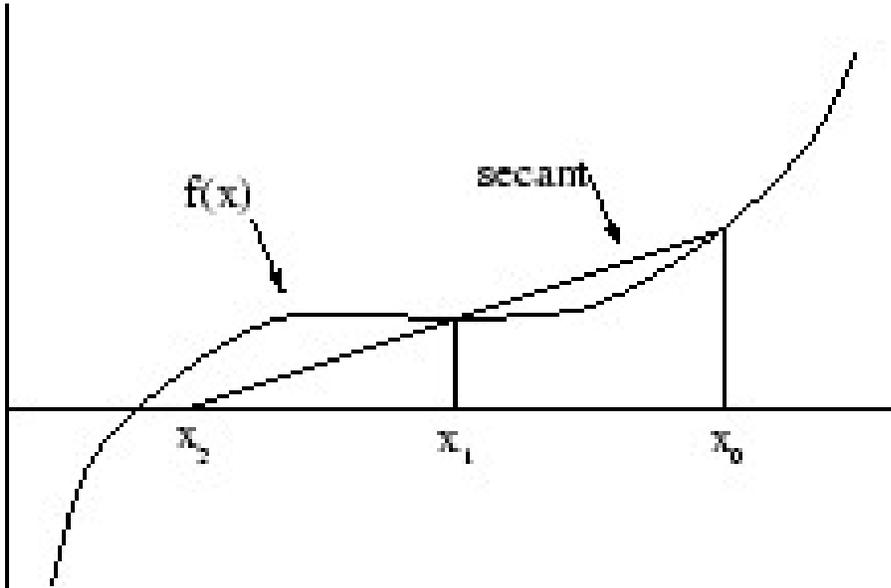

if  $P$  is a simple solution, the Newton-Raphson has  $R=2$  as quadratic

Secant Method

The Newton-Raphson method requires the evaluation of two functions at each iteration and the derivative of the function

The Secant method only needs one evaluation of  $f(x)$

if  $f(x)$  has only one root,  $R=1.618$ , which is close to Newton raphson

[http://pathfinder.scar.utoronto.ca/~dyer/csc57/book\\_P/node36.html](http://pathfinder.scar.utoronto.ca/~dyer/csc57/book_P/node36.html)

$$m = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$$

$$x_{k+1} = x_k - f(x_k) * \left( \frac{x_k - x_{k-1}}{f(x_k) - f(x_{k-1}))} \right)$$

I	X	F(xk)	X(k+i)
0	0	-0.5	0.03414
1	1	0.03415	0.594
2	0.594	0.597	0.50798
3	0.50798	-0.0135	0.5238

The solution of linear system

$$AX=B$$

E.X.

$$6x+3y+2z=29$$

$$3x+y+3z=17$$

$$2x+3y+7z=21$$

$$\begin{bmatrix} 6 & 3 & 2 \\ 3 & 1 & 2 \\ 2 & 3 & 2 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 29 \\ 21 \\ 21 \end{bmatrix}$$

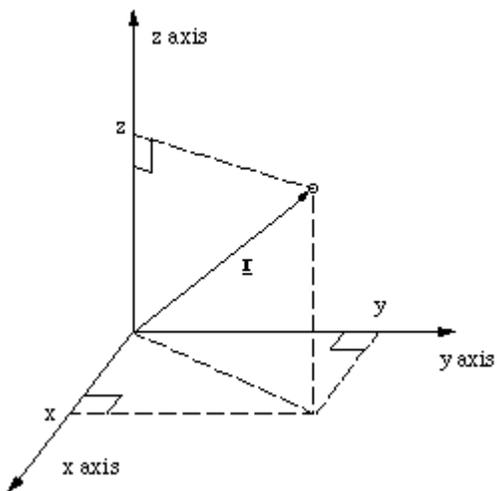

$$A \quad x = b$$

<http://www.cs.purdue.edu/homes/cs314/>

N Dimensional Vector:  $x=(x_1, x_2, x_3, \dots, x_n)$

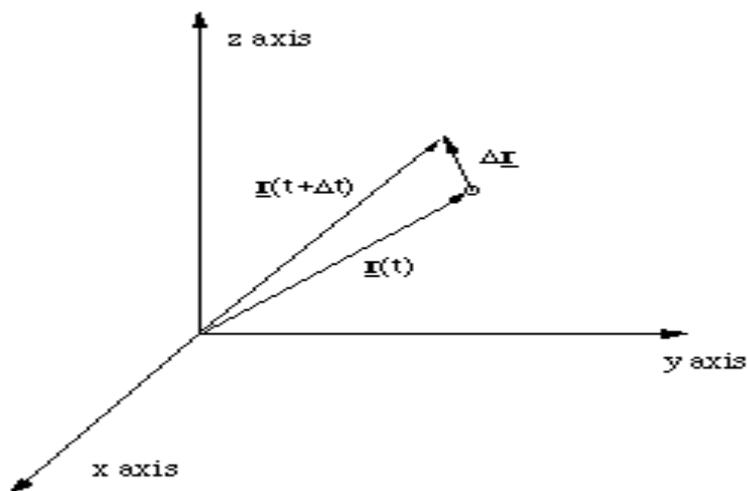

N Dimensional space: the set of all N dimensional vectors

When a vector is used to determine a position it is called a position vector

[http://www.ch.ic.ac.uk/local/physical/mi\\_2.html](http://www.ch.ic.ac.uk/local/physical/mi_2.html)

When a vector is used to denote movement between two points in space it is called the displacement vector

[http://www.ch.ic.ac.uk/local/physical/mi\\_2.html](http://www.ch.ic.ac.uk/local/physical/mi_2.html)

Properties of vectors

Equality:  $x=y$  only if  $x_j = y_j$  for all  $j = 1,2,3,\dots,n$

Sum:  $X + Y = x_1 + y_1, x_2 + y_2, x_3 + y_3 \dots x_n + y_n$

Negative:  $-Y = -y_1, -y_2, -y_3 \dots -y_n$

Difference:  $X - Y = x_1 - y_1, x_2 - y_2, x_3 - y_3 \dots x_n - y_n$

Scalar multiplication:  $cX = cx_1, cx_2, cx_3 \dots cx_n$

Linear combination:  $cX + dY = cx_1 + dy_1, cx_2 + dy_2, cx_3 + dy_3 \dots cx_n + dy_n$

Dot product:  $X \cdot Y = x_1 \cdot y_1, x_2 \cdot y_2, x_3 \cdot y_3 \dots x_n \cdot y_n$

Norm or Euclidean norm:  $\|X\| = (x_1^2 + x_2^2 + x_3^2 \dots x_n^2)^{1/2}$

In scalar multiplication  $cX$ , if  $|c| > 1$ , then  $cX$  is a stretched version of  $X$  and if  $|c| < 1$ , then  $cX$  is a shrunken version of  $X$ .  $\|cX\| = |c| \|X\|$

Distance of point in space:  $X - Y = x_1 - y_1, x_2 - y_2, x_3 - y_3 \dots x_n - y_n$ .  $\|X - Y\| = (x_1^2 + x_2^2 + x_3^2 \dots x_n^2)^{1/2}$

E.X.

$x = (-1, 3, 2), y = (3, 5, 2)$

$x + y = (2, 8, 4)$

$x - y = (-4, -2, 0)$

$2x = (-2, 6, 4)$

$\|x\| = \sqrt{5}$

Displacement:  $y - x = (4, 2, 0)$

Distance:  $\|y - x\| = \sqrt{20} = 2\sqrt{5}$

Sometimes we write vectors in columns

$$X = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_m \end{bmatrix}$$

<http://wpcontent.answers.com/math/3/8/1/381890b4e3dc92930bff4ab8da4e5e5e.png>

We use superscript "′" or "̄" to convert a vector from a row to column, vice versa.

Vector algebra

Commutative:  $Y + X = X + Y$

Additive identity:  $X = X + 0 = 0 + X$

Additive inverse:  $X - X = X + (-X) = 0$

associative:  $X + (Y + Z) = (X + Y) + Z$

Distributive with scalar:  $(a + b) X = aX + bX$

Distributive with vector:  $a(X + Y) = aX + aY$

Associative with vector:  $a(bX) = (ab)X$

Matrices

If  $A$  is a matrix, then  $a_{ij}$  denote the number at  $i$ , and  $j$  ( $i$  is the row and  $j$  is the column)

If  $A$  is a  $M \times N$  matrix, then it has  $M$  rows and  $N$  columns

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \end{bmatrix}$$

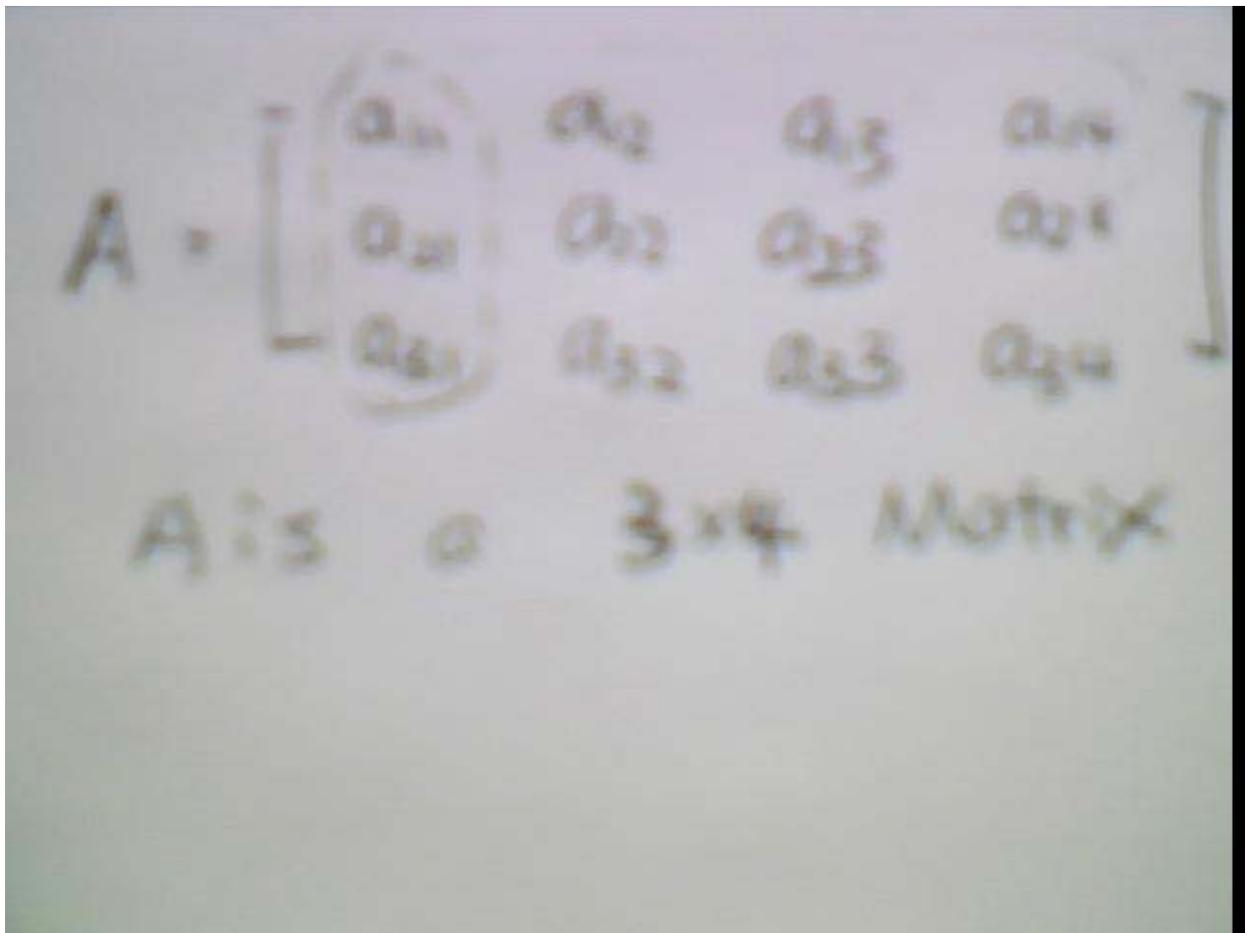

A is a 3x4 Matrix

You can see a M\*N matrix as M rows of N dimensional vector

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \end{bmatrix}$$

A is a 3x4 Matrix

Or as N columns of M dimensional vector

Operations with matrices

Equality:  $A = B$  only if  $a_{ij} = b_{ij}$

Sum:  $A + B = (a_{ij} + b_{ij})_{m \times n}$

**Negation:**  $-A = (-a_{ij})_{m \times n}$

Difference:  $A - B = (a_{ij} - b_{ij})_{m \times n}$

Scalar multiplication:  $cA = (ca_{ij})_{m \times n}$

Weighted Sum:  $pA + qB = (pa_{ij} + qb_{ij})_{m \times n}$

E.X.

$$A = \begin{bmatrix} 2 & 1 \\ 4 & 6 \\ 3 & 5 \end{bmatrix} \quad B = \begin{bmatrix} 1 & 7 \\ 6 & 2 \\ 5 & 1 \end{bmatrix}$$
$$3A + 2B = \begin{bmatrix} 8 & 11 \\ 24 & 22 \\ 15 & 8 \end{bmatrix}$$

### Properties

Commutative:  $X + Y = Y + X$

Additive identity:  $X + 0 = 0 + X$

Additive inverse:  $X - X = X + (-X) = 0$

Associative:  $X + (Y + Z) = (X + Y) + Z$

Distributive with scalars:  $(a + b) X = aX + bX$

Distributive with matrices:  $a(X + Y) = aX + aY$

Distributive with matrices:  $a(bX) = (ab)X$

### Matrix Multiplication

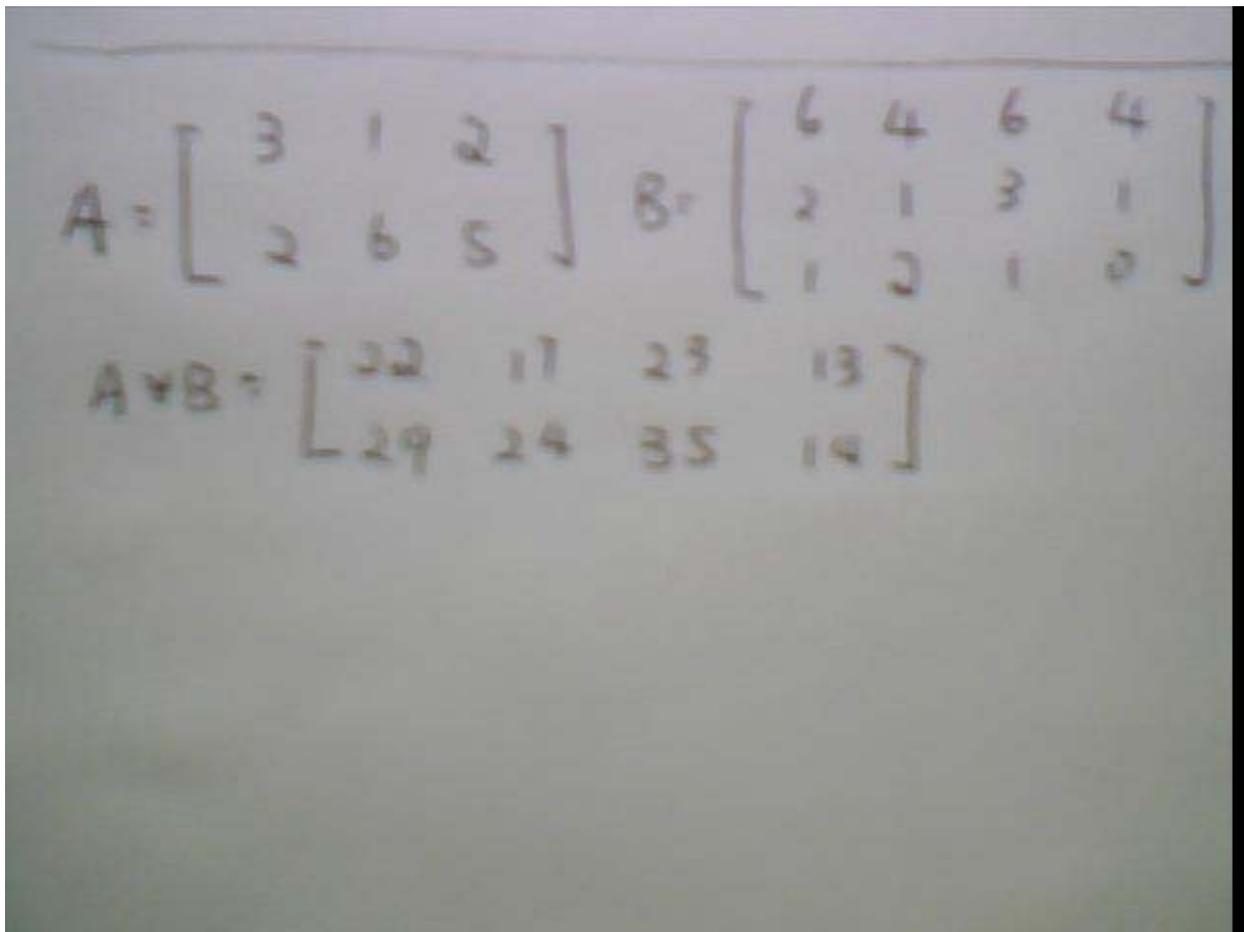

$A \cdot B = C$

$$A=[a_{ik}], M \times N$$

$$B=[b_{kj}] N \times P$$

$$C = \sum a_{jk} b_{kxj}, M \times P$$

E.X.

A photograph of a whiteboard showing a handwritten example of matrix addition. The matrix A is a 2x3 matrix with elements 3, 1, 2 in the first row and 2, 6, 5 in the second row. The matrix B is a 2x4 matrix with elements 6, 4, 6, 4 in the first row and 2, 1, 3, 1 in the second row. The resulting matrix A+B is a 2x4 matrix with elements 22, 17, 25, 13 in the first row and 29, 24, 35, 14 in the second row.

$$A = \begin{bmatrix} 3 & 1 & 2 \\ 2 & 6 & 5 \end{bmatrix} \quad B = \begin{bmatrix} 6 & 4 & 6 & 4 \\ 2 & 1 & 3 & 1 \end{bmatrix}$$
$$A+B = \begin{bmatrix} 22 & 17 & 25 & 13 \\ 29 & 24 & 35 & 14 \end{bmatrix}$$

Special matrices

Zero matrix:

$$M = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

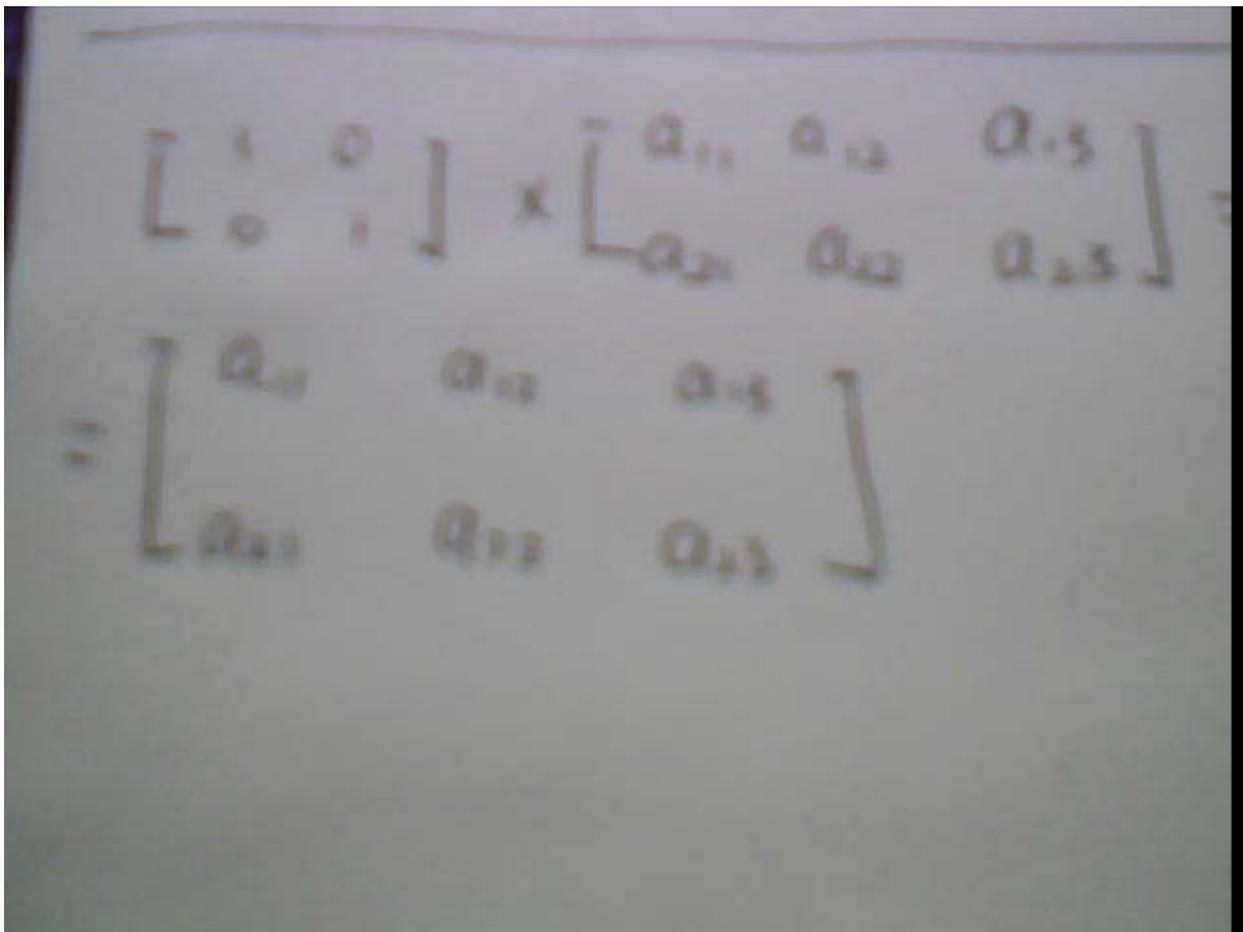

<http://upload.wikimedia.org/math/6/6/3/6638ff38b6275ae82451b617f58e5b96.png>

Identity matrix:  $I_n = (a_{ij})_{n \times n}$  where  $(a_{ij}) = 1$  when  $i = j$  and  $= 0$  when  $i \neq j$

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

[http://help.adobe.com/en\\_US/FlashPlatform/beta/reference/actionsript/3/images/identityMatrix.jpg](http://help.adobe.com/en_US/FlashPlatform/beta/reference/actionsript/3/images/identityMatrix.jpg)

E.X.

The image shows a handwritten example of matrix multiplication on a piece of paper. It illustrates the multiplication of a 2x2 identity matrix by a 2x3 matrix. The identity matrix is written as  $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$  and the second matrix is  $\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \end{bmatrix}$ . The result is shown as  $\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \end{bmatrix}$ .

#### Properties of matrix multiplication

$(AB)C = A(BC)$  : associative for multiplication

$IA = AI = A$ : identity matrix

$A(B + C) = AB + AC$  : left distributive

$(A + B).C = AC + BC$ : right distributive

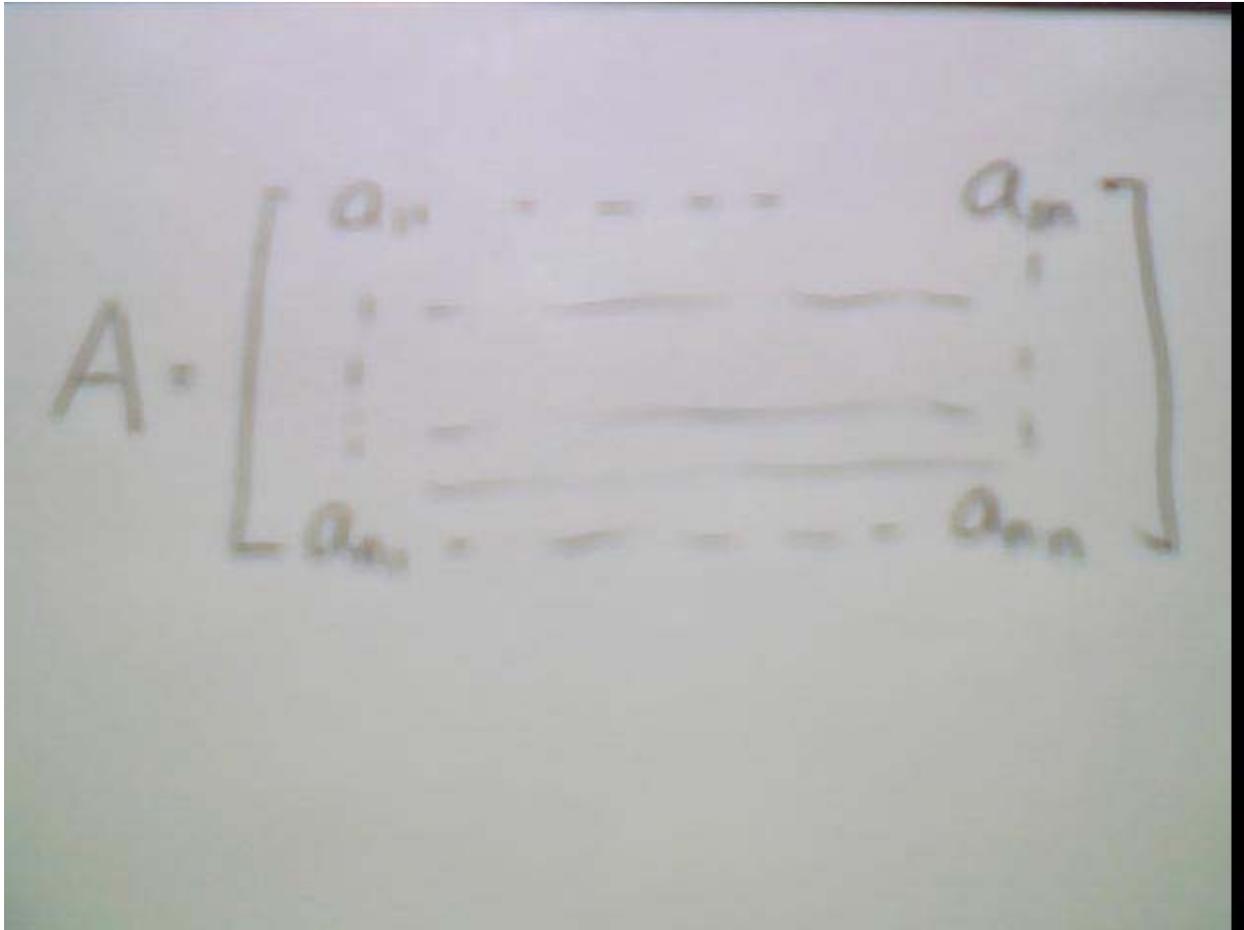

Note: No commutative property:  $A*B$  is not  $B*A$

Inverse of a nonsingular matrix

A  $n \times n$  matrix  $A$  is called non-singular or invertible if there exist a  $N \times N$  matrix such that  $A \cdot B = B \cdot A = I$ , if there is such  $B$ ,  $A$  is singular, If  $B$  can be found, we can write  $B=A^{-1}$ ,  $A=B^{-1}$  or  $A \cdot A^{-1}=A^{-1} \cdot A$ .

Determinants

Assume

that

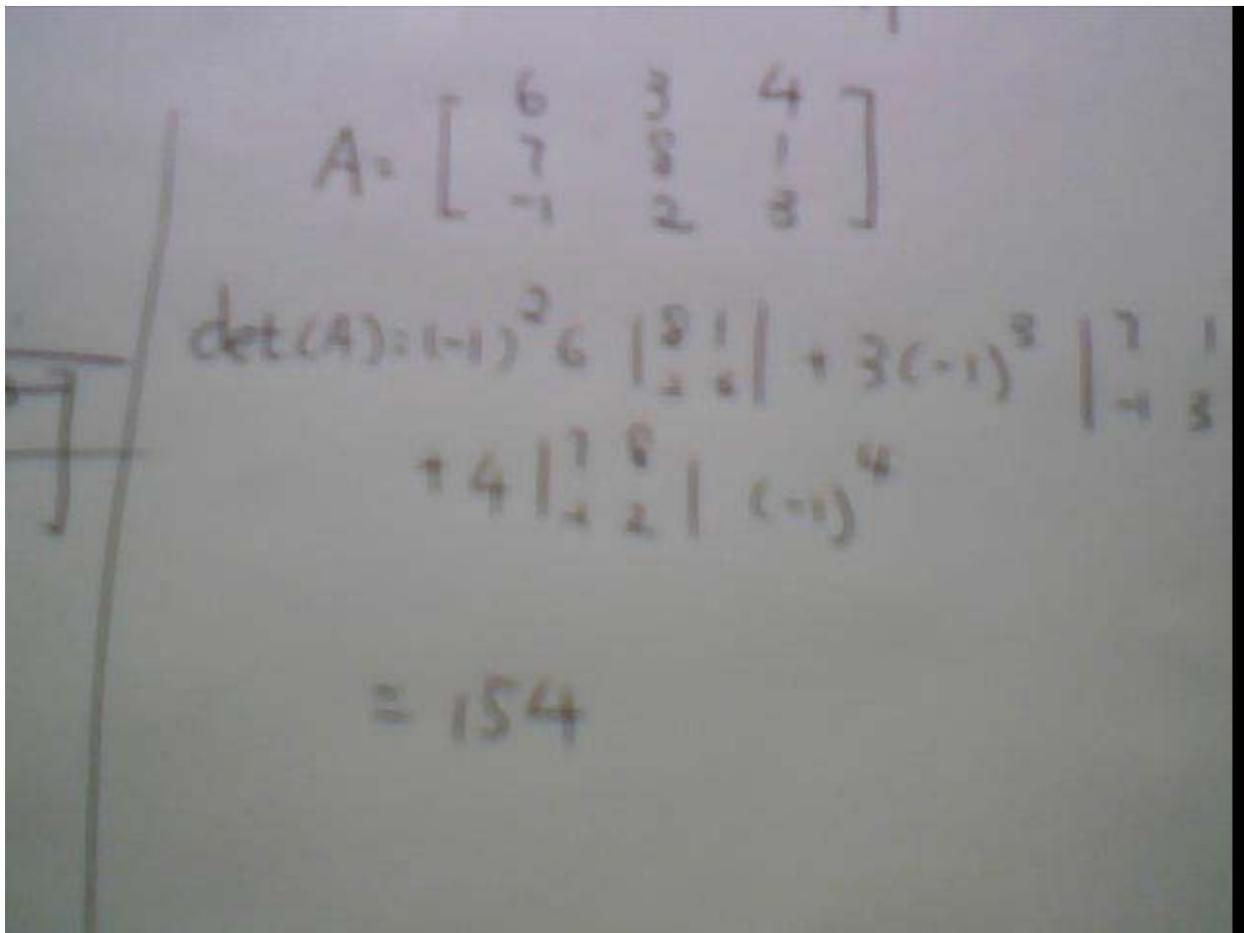

$$\det(A) = \begin{vmatrix} a_{11} & \dots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \dots & a_{nn} \end{vmatrix}$$

Determinants is scalar

If  $A = [a_{ij}]$ ,  $\det(a) = a_{ij}$

Defining determinants in a recursive way, eliminating row  $i$  and column  $j$  from  $A$ .

E.X.

### Upper Triangular system

$A=[a_{ij}]$  is called upper triangular if  $a_{ij}=0$  when  $i>j$ .

$$U_5 = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 & 4 \\ 0 & 0 & 1 & 3 & 6 \\ 0 & 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix};$$

E.X.

Lower triangular

$A=[a_{ij}]$  is called lower triangular if  $a_{ij}=0$  when  $i<j$

$$\begin{bmatrix} 0 & 0 & 0 & \cdots & 0 \\ a_{21} & 0 & 0 & \cdots & 0 \\ a_{31} & a_{32} & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & 0 \end{bmatrix}$$

E.X.

### Upper triangular system of linear equations

$$\begin{aligned} a_{1,1}x_1 + a_{1,2}x_2 + a_{1,3}x_3 + \dots + a_{1,n-1}x_{n-1} + a_{1,n}x_n &= b_1 \\ a_{2,2}x_2 + a_{2,3}x_3 + \dots + a_{2,n-1}x_{n-1} + a_{2,n}x_n &= b_2 \\ a_{3,3}x_3 + \dots + a_{3,n-1}x_{n-1} + a_{3,n}x_n &= b_3 \\ &\vdots \\ a_{n-1,n-1}x_{n-1} + a_{n-1,n}x_n &= b_{n-1} \\ a_{n,n}x_n &= b_n \end{aligned}$$

Backward substitution: solve for  $x_n$  in the last equation, plug it into the second last equation

$$x_k = (b_k - \sum_{j=k+1}^n a_{kj}x_j) / a_{kk}$$

E.X.  $3x + 4y + z = 2$

$$3y + 2z = 1$$

$$5z = 10$$

Using backward substitution, we get  $z=2, y=-1, x=4/3$ .

### **Gauss Elimination**

Usually system of linear equations are not upper triangular

With Gauss elimination we can convert an arbitrary system of linear equation into upper triangular and solve with backward substitution.

Gauss elimination uses some elementary transformations of the system of equations that do not affect the solution

1. Interchange
2. Scaling
3. replacement

### Interchange

The order of two equations can be change and it will not affect the solution

$$\begin{bmatrix} 1 & 3 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 19 \\ 21 \end{bmatrix}$$

⇓

$$\begin{bmatrix} 2 & 7 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 21 \\ 19 \end{bmatrix}$$

### Scaling

Multiplying an equation by a constant will not affect the solution

$$\begin{bmatrix} 1 & 3 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 19 \\ 21 \end{bmatrix} \times 2$$

⇓

$$\begin{bmatrix} 2 & 6 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 38 \\ 21 \end{bmatrix}$$

### Replacement

A equation can be replaced by the sum of itself and a non-zero multiple of another equation without affecting the solution

$$\begin{bmatrix} 1 & 3 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 19 \\ 21 \end{bmatrix} \ominus$$

~~1 + 2~~    ① + ② × 2

$$\begin{bmatrix} 5 & 17 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 61 \\ 21 \end{bmatrix}$$

We used these transformations to convert a system of linear equations to upper triangular and then solve it with backward substitution

$$\begin{aligned} x + 3y + 4z &= 19 \\ 8x + 9y + 3z &= 35 \\ x + y + z &= 6 \end{aligned} \Rightarrow \begin{bmatrix} 1 & 3 & 4 \\ 8 & 9 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 19 \\ 35 \\ 6 \end{bmatrix}$$

Augment matrix

$$\begin{bmatrix} 1 & 3 & 4 & 19 \\ 8 & 9 & 3 & 35 \\ 1 & 1 & 1 & 6 \end{bmatrix}$$

For all the row's starting at row= $i=1$

Step one:

Name element  $a_{ii}$  as the pivot,  $a_{ii}$ , we have to make sure that the pivot is 1, otherwise divide the whole row by the value of the pivot.

$$\Rightarrow \begin{bmatrix} 1 & 3 & 4 & 19 \\ 8 & 9 & 3 & 35 \\ 1 & 1 & 1 & 6 \end{bmatrix}$$

Step two

We need to make the matrix upper triangular we need to make the element under the pivot 0, we multiply the pivot by the -value under the pivot and added the row.

$$\Rightarrow \begin{bmatrix} 1 & 3 & 4 & 19 \\ 0 & -15 & -29 & -117 \\ 1 & 1 & 1 & 0 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 1 & 3 & 4 & 19 \\ 0 & -15 & -29 & -117 \\ 0 & 1 & -3 & -19 \end{bmatrix}$$

Step three

Now the pivot is  $a_{22} = -15$ , repeat step one and two

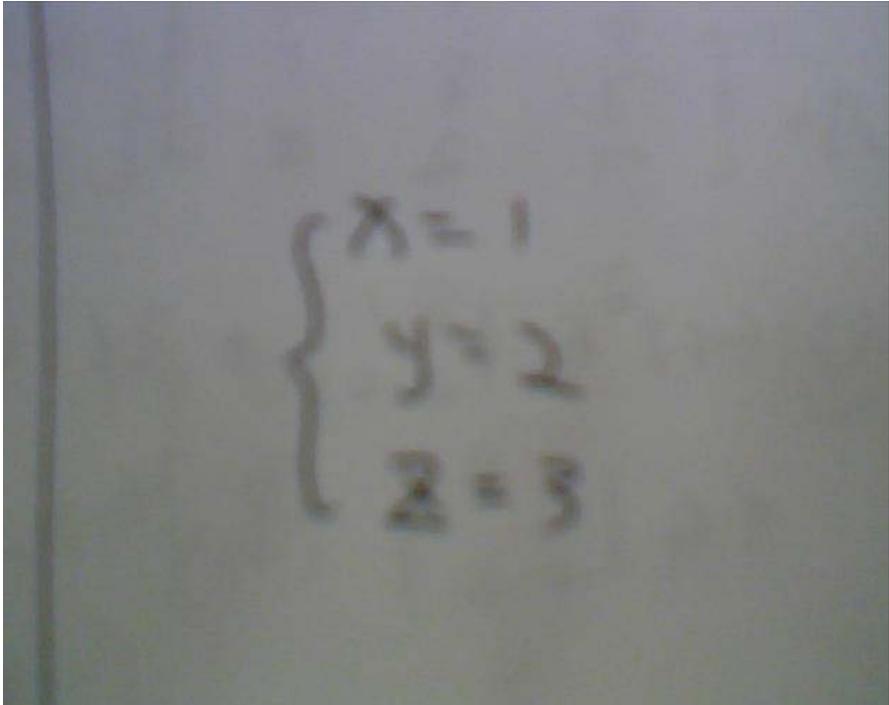

$$\Rightarrow \begin{bmatrix} 1 & 3 & 4 & 19 \\ 0 & 1 & \frac{29}{15} & \frac{117}{15} \\ 0 & -2 & -3 & -13 \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 1 & 3 & 4 & 19 \\ 0 & 1 & \frac{29}{15} & \frac{117}{15} \\ 0 & 0 & \frac{13}{15} & \frac{13}{15} \end{bmatrix}$$

$$\Rightarrow \begin{bmatrix} 1 & 3 & 0 & 19 \\ 0 & 1 & 29/5 & 117/5 \\ 0 & 0 & 1 & 5 \end{bmatrix}$$

Step four

Backward substitution

Note: if the pivot is 0, then swap rows

### Implementing Gauss Elimination to Matlab

File gauss.m

```
function x = gauss(A,B)
```

```
