Lecture 17: CRHF & Merkle-Damgård Construction

Lecture 17: CRHF & Merkle-Damgård Construction

Recall

 \bullet Collision-resistant Hash Function family from domain ${\cal D}$ to range ${\cal R}$ is a set of hash functions

$$\mathcal{H} = \{ h^{(i)} \colon i \in \mathcal{I} \},\$$

where \mathcal{I} is the set of indices and each function $h^{(i)} \colon \mathcal{D} \to \mathcal{R}$

- Any efficient adversary given h⁽ⁱ⁾, where i ← I, can output x, x' ∈ D such that h⁽ⁱ⁾(x) = h⁽ⁱ⁾(x') only with negligible probability
- One bit compressing (i.e., |D| = 2 |R|) can be constructed from the hardness of the discrete logarithm assumption as follows. Let the discrete logarithm problem be hard in the group G, then for b ∈ {0,1} and x ∈ Z_{|G|}, we have:

$$egin{aligned} &h^{(y)}\colon \{0,1\} imes \mathbb{Z}_{|G|}
ightarrow G\ &h^{(y)}(b,x)=y^bg^x\ &\mathcal{H}=\{h^{(y)}\colon y\in G\} \end{aligned}$$

Lecture 17: CRHF & Merkle-Damgård Construction

t-bit Compression

We can construct a *t*-bit compression function as follows: Let $b \in \{0, 1\}^t$ and $y^{(1)}, \ldots, y^{(t)} \in \mathbb{Z}_{|G|}$.

$$h^{(y^{(1)},\ldots,y^{(t)})}(b,x) = y^{(1)^{b_1}}\cdots y^{(t)^{b_t}}g^x$$

Each function is indexed by $(y^{(1)}, \ldots, y^{(t)})$ and each $y^{(i)} \in \{0, 1\}^n$. So, index size is tn.

- Prove: If Discrete Logarithm assumption holds in G then the construction above is a CRHF, where t = poly(n)
- Prove: If $\mathcal{H}^{(n)}$ is a CRHF family with functions $\{0,1\}^{n+1} \rightarrow \{0,1\}^n$, for all large enough *n*, then the construction above is a CRHF family, where t = poly(n)
- Think: What is the difference between the above two theorems

(日本)(周本)(日本)(本)(日本)(日本)

In particular, with t = n and G = {0,1}ⁿ, the previously constructed function is a length halving family of hash functions where all functions are {0,1}²ⁿ → {0,1}ⁿ

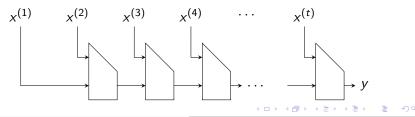

- We are interested in hashing $\{0,1\}^{tn}$ down to $\{0,1\}^{n}$
- One-bit compression at a time needs $(t-1)n \times n$ size indices. Can we do better?

-

Tree-based Hashing

- Let $\mathcal H$ be a CRHF family with functions $\{0,1\}^{2n} \to \{0,1\}^n$ and key size K
- We will construct CRHF family $\mathcal{H}^{(t)}$ with functions $\{0,1\}^{tn} \to \{0,1\}^n$ and key size K, for $t \ge 2$
- Let x ∈ {0,1}^{tn} be represented as (x⁽¹⁾,...,x^(t)), where each x⁽ⁱ⁾ ∈ {0,1}ⁿ. The function is calculated in an iterated fashion as represented below. Each box represents an application of a function h ∈ H and the output of the hash function is y. Call this new function itr_t(h) function. So, we have H^(t) = {itr_t(h): h ∈ H}.

Lecture 17: CRHF & Merkle-Damgård Construction

Proof

- Our adversary *A* on input a hash function h feeds itr_t(h) function to *A**
- Suppose \mathcal{A}^* produces $x = (x^{(1)}, \dots, x^{(t)})$ and $z = (z^{(1)}, \dots, z^{(t)})$ such that it is a collision of the function $\operatorname{itr}_t(h)$ function
- Suppose the input to the last *h*-box in the evaluation of $\operatorname{itr}_t(h)(x)$ is *a* and the input to the last *h*-box in the evaluation of $\operatorname{itr}_t(h)(z)$ is *b*. We know that the output of the last *h*-box is same in these two cases. If $a \neq b$, then we have found a collision.
- If a = b, then the output of the second last h-box is identical in itr_t(h)(x) and itr_t(h)(z) evaluation. Therefore, we can recurse on (x⁽¹⁾,...,x^(t-1)) and (z⁽¹⁾,...,z⁽¹⁾t - 1) that also produce a collision (i.e. the output of the second last h-box)
