Lecture 09: Shamir Secret Sharing (Lagrange Interpolation)

#### Recall: Goal

We want to

Share a secret  $s \in \mathbb{Z}_p$  to n parties, such that  $\{1,\dots,n\} \subseteq \mathbb{Z}_p$ ,

Any two parties can reconstruct the secret s, and

No party alone can predict the secret s

# Recall: Secret Sharing Algorithm

```
SecretShare(s,n)

Pick a random line \ell(X) that passes through the point (0,s)

This is done by picking a_1 uniformly at random from the set \mathbb{Z}_p

And defining the polynomial \ell(X) = a_1X + s

Evaluate s_1 = \ell(X = 1), \ s_2 = \ell(X = 2), \dots, \ s_n = \ell(X = n)

Secret shares for party 1, party 2, ..., party n are s_1, s_2, \ldots, s_n, respectively
```

## Recall: Reconstruction Algorithm

SecretReconstruct $(i_1, s^{(1)}, i_2, s^{(2)})$ 

Reconstruct the line  $\ell'(X)$  that passes through the points  $(i_1, s^{(1)})$  and  $(i_2, s^{(2)})$ 

We will learn a new technique to perform this step, referred to as the Lagrange Interpolation

Define the reconstructed secret  $s' = \ell'(0)$ 

#### General Goal

We want to

Share a secret  $s \in \mathbb{Z}_p$  to n parties, such that  $\{1,\ldots,n\} \subseteq \mathbb{Z}_p$ ,

Any t parties can reconstruct the secret s, and

Less than t parties cannot predict the secret s

# Shamir's Secret Sharing Algorithm

```
SecretShare(s, n)
```

Pick a polynomial p(X) of degree  $\leq (t-1)$  that passes through the point (0,s)

This is done by picking  $a_1, \ldots, a_{t-1}$  independently and uniformly at random from the set  $\mathbb{Z}_p$ 

And defining the polynomial

$$\ell(X) = a_{t-1}X^{t-1} + a_{t-2}X^{t-2} + \dots + a_1X + s$$

Evaluate 
$$s_1 = p(X = 1)$$
,  $s_2 = p(X = 2)$ , ...,  $s_n = p(X = n)$ 

Secret shares for party 1, party 2, ..., party n are  $s_1, s_2, \ldots, s_n$ , respectively

# Shamir's Reconstruction Algorithm

```
SecretReconstruct(i_1, s^{(1)}, i_2, s^{(2)}, \dots, i_t, s^{(t)})
```

Use Lagrange Interpolation to construct a polynomial p'(X) that passes through  $(i_1, s^{(1)}), \ldots, (i_t, t^{(t)})$  (we describe this algorithm in the following slides)

Define the reconstructed secret s' = p'(0)

#### Lagrange Interpolation: Introduction I

Consider the example we were considering in the previous lecture

The secret was s = 3

Secret shares of party 1, 2, 3, and 4, were 0, 2, 4, and 1, respectively

Suppose party 2 and party 3 are trying to reconstruct the secret

Party 2 has secret share 2, and Party 3 has secret share 4

We are interested in finding the line that passes through the points (2,2) and (3,4)

### Lagrange Interpolation: Introduction II

#### Subproblem 1:

Let us find the line that passes through (2,2) and (3,0)

Note that at X = 3 this line evaluates to 0, so

X = 3 is a root of the line

So, the line has the equation  $\ell_1(X) = c \cdot (X-3)$ ,

where c is a suitable constant

Now, we find the value of c such that  $\ell_1(X)$  passes through the point (2,2)

So, we should have  $c \cdot (2-3) = 2$ , i.e., c = 3

 $\ell_1(X) = 3 \cdot (X - 3)$  is the equation of that line

#### Lagrange Interpolation: Introduction III

#### Subproblem 2:

Let us find the line that passes through (2,0) and (3,4)

Note that at X = 2 this line evaluates to 0, so

X = 2 is a root of the line

So, the line has the equality  $\ell_2(X) = c \cdot (X-2)$ ,

where c is a suitable constant

Now, we find the value of c such that  $\ell_2(X)$  passes through the point (3,4)

So, we should have  $c \cdot (3-2) = 4$ , i.e. c = 4

$$\ell_2(X) = 4 \cdot (X - 2)$$

### Lagrange Interpolation: Introduction IV

Putting Things Together:

Define 
$$\ell'(X) = \ell_1(X) + \ell_2(X)$$

That is, we have

$$\ell'(X) = 3 \cdot (X - 3) + 4 \cdot (X - 2)$$

Evaluation of  $\ell'(X)$  at X = 0 is

$$s' = \ell'(X = 0) = 3 \cdot (-3) + 4 \cdot (-2) = 3 \cdot 2 + 4 \cdot 3 = 1 + 2 = 3$$

### Uniqueness of Polynomial I

We shall prove the following result

#### $\mathsf{Theorem}$

There is a unique polynomial of degree at most d that passes through  $(x_1, y_1)$ ,  $(x_2, y_2)$ , ...,  $(x_{d+1}, y_{d+1})$ 

If possible, let there exist two distinct polynomials of degree  $\leq d$  such that they pass through the points  $(x_1, y_1)$ ,  $(x_2, y_2)$ , ...,  $(x_{d+1}, y_{d+1})$ 

Let the first polynomial be

$$p(X) = a_d X^d + a_{d-1} X^{d-1} + \dots + a_1 X + a_0$$

Let the second polynomial be

$$p'(X) = a'_d X^d + a'_{d-1} X^{d-1} + \dots + a'_1 X + a'_0$$

### Uniqueness of Polynomial II

Let  $p^*(X)$  be the polynomial that is the difference of the polynomials p(X) and p'(X), i.e.,

$$p^*(X) = p(X) - p'(X) = (a_d - a'_d)X^d + \dots (a_1 - a'_1)X + (a_0 - a'_0)$$

**Observation**. The degree of  $p^*(X)$  is  $\leq d$ 

## Uniqueness of Polynomial III

For  $i \in \{1, ..., d+1\}$ , note that at  $X = x_i$  both p(X) and p'(X) evaluate to  $y_i$ So, the polynomial  $p^*(X)$  at  $X = x_i$  evaluates to  $y_i - y_i = 0$ , i.e.  $x_i$  is a root of the polynomial  $p^*(X)$ 

**Observation.** The polynomial  $p^*(X)$  has roots  $X = x_1$ ,  $X = x_2, \ldots, X = x_{d+1}$ 

#### Uniqueness of Polynomial IV

We will use the following result

#### Theorem (Schwartz–Zippel, Intuitive)

A non-zero polynomial of degree d has at most d roots (over any field)

#### Conclusion.

Based on the two observations above, we have a  $\leq d$  degree polynomial  $p^*(X)$  that has at least (d+1) distinct roots  $x_1, \ldots, x_{d+1}$ 

This implies, by Schwartz–Zippel Lemma, that the polynomial is the zero-polynomial.

That is,  $p^*(X) = 0$ .

This implies that p(X) and p'(X) are identical

This contradicts the initial assumption that there are two distinct polynomials p(X) and p'(X)

### Summary

The proof in the previous slides proves that

Given a set of points  $(x_1, y_1)$ , ...,  $(x_{d+1}, y_{d+1})$ 

There is a <u>unique</u> polynomial of degree at most d that passes through all of them!

#### Lagrange Interpolation I

Suppose we are interested in constructing a polynomial of degree  $\leq d$  that passes through the points  $(x_1, y_1), \ldots, (x_{d+1}, y_{d+1})$ 

#### Lagrange Interpolation II

#### **Subproblem** *i*:

We want to construct a polynomial  $p_i(X)$  of degree  $\leq d$  that passes through  $(x_i, y_i)$  and  $(x_j, 0)$ , where  $j \neq i$  So,  $\{x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{d+1}\}$  are roots of the polynomial  $p_i(X)$ 

Therefore, the polynomial  $p_i(X)$  looks as follows

$$p_i(X) = c \cdot (X - x_1) \cdots (X - x_{i-1})(X - x_{i+1}) \cdots (X - x_{d+1})$$

Tersely, we will write this as

$$p_i(X) = c \cdot \prod_{\substack{j \in \{1, \dots, d+1\} \\ \text{such that } j \neq i}} (X - x_j)$$

### Lagrange Interpolation III

Now, to evaluate c we will use the property that  $p_i(x_i) = y_i$ 

Observe that the following value of c suffices

$$c = \frac{y_i}{\prod_{\substack{j \in \{1, \dots, d+1\} \\ \text{such that } j \neq i}} (x_i - x_j)}$$

So, the polynomial  $p_i(X)$  that passes through  $(x_i, y_i)$  and  $(x_j, 0)$ , where  $j \neq i$  is

$$p_i(X) = \frac{y_i}{\prod_{\substack{j \in \{1, \dots, d+1\} \text{ such that } j \neq i}} (X_i - X_j)} \cdot \prod_{\substack{j \in \{1, \dots, d+1\} \text{ such that } j \neq i}} (X - X_j)$$

Observe that  $p_i(X)$  has degree d

### Lagrange Interpolation IV

#### **Putting Things Together:**

Consider the polynomial

$$p(X) = p_1(X) + p_2(X) + \ldots + p_{d+1}(X)$$

This is the desired polynomial that passes through  $(x_i, y_i)$ 

#### Claim

The polynomial p(X) passes through  $(x_i, y_i)$ , for  $i \in \{1, \dots, d+1\}$ 

# Lagrange Interpolation V

#### Proof.

Note that, for  $j \in \{1, \dots, d+1\}$ , we have

$$p_j(x_i) = \begin{cases} y_i, & \text{if } j = i \\ 0, & \text{otherwise} \end{cases}$$

Therefore, 
$$p(x_i) = \sum_{j=1}^{d+1} p_j(x_i) = y_i$$

## Summary of Interpolation

Given points  $(x_1, y_1), \ldots, (x_{d+1}, y_{d+1})$ 

Lagrange Interpolation provides <u>one</u> polynomial of degree  $\leq d$  polynomial that passes through all of them

Theorem 1 states that this  $\leqslant d$  degree polynomial is unique

## Example for Lagrange Interpolation I

Let us find a degree  $\leq$  2 polynomial that passes through the points  $(x_1, y_1)$ ,  $(x_2, y_2)$ , and  $(x_3, y_3)$ 

Subproblem 1:

We want to find a degree  $\leq 2$  polynomial that passes through the points  $(x_1, y_1)$ ,  $(x_2, 0)$ , and  $(x_3, 0)$  The polynomial is

$$p_1(X) = \frac{y_1}{(x_1 - x_2)(x_1 - x_3)}(X - x_2)(X - x_3)$$

#### Example for Lagrange Interpolation II

#### Subproblem 2:

We want to find a degree  $\leq 2$  polynomial that passes through the points  $(x_1,0)$ ,  $(x_2,y_2)$ , and  $(x_3,0)$ . The polynomial is

$$p_2(X) = \frac{y_2}{(x_2 - x_1)(x_2 - x_3)}(X - x_1)(X - x_3)$$

#### Subproblem 3:

We want to find a degree  $\leq 2$  polynomial that passes through the points  $(x_1,0)$ ,  $(x_2,0)$ , and  $(x_3,y_3)$ . The polynomial is

$$p_2(X) = \frac{y_3}{(x_3 - x_1)(x_3 - x_2)}(X - x_1)(X - x_2)$$

### Example for Lagrange Interpolation III

Putting Things Together: The reconstructed polynomial is

$$p(X) = p_1(X) + p_2(X) + p_3(X)$$

#### Conclusion

This completes the description of Shamir's Secret Sharing algorithm. In the following lectures we will argue its security.
