## Cryptography: Message Authentication Code

# Announcements

- Homework 1 handed out on Sept 1, due on Sept 10
- Will have first quiz on Sept 8

# Limitation of Using Hash Functions for Authentication

- Require an authentic channel to transmit the hash of a message
  - anyone can compute the hash value of a message, as the hash function is public
  - not always possible
- How to address this?
  - use more than one hash functions
  - use a key to select which one to use

# Hash Family

- A hash family is a four-tuple  $(X, Y, K, H)$ , where
  - $X$  is a set of possible messages
  - $Y$  is a finite set of possible message digests
  - $K$  is the keyspace
  - For each  $K \in K$ , there is a hash function  $h_K \in H$ . Each  $h_K: X \rightarrow Y$
- Alternatively, one can think of  $H$  as a function  $K \times X \rightarrow Y$

# Message Authentication Code

- A MAC scheme is a hash family, used for message authentication
- $MAC = C_K(M)$
- The sender and the receiver share  $K$
- The sender sends  $(M, C_K(M))$
- The receiver receives  $(X, Y)$  and verifies that  $C_K(X)=Y$ , if so, then accepts the message as from the sender
- To be secure, an adversary shouldn't be able to come up with  $(X', Y)$  such that  $C_K(X')=Y$ .

# Example of Insecure Hash Families

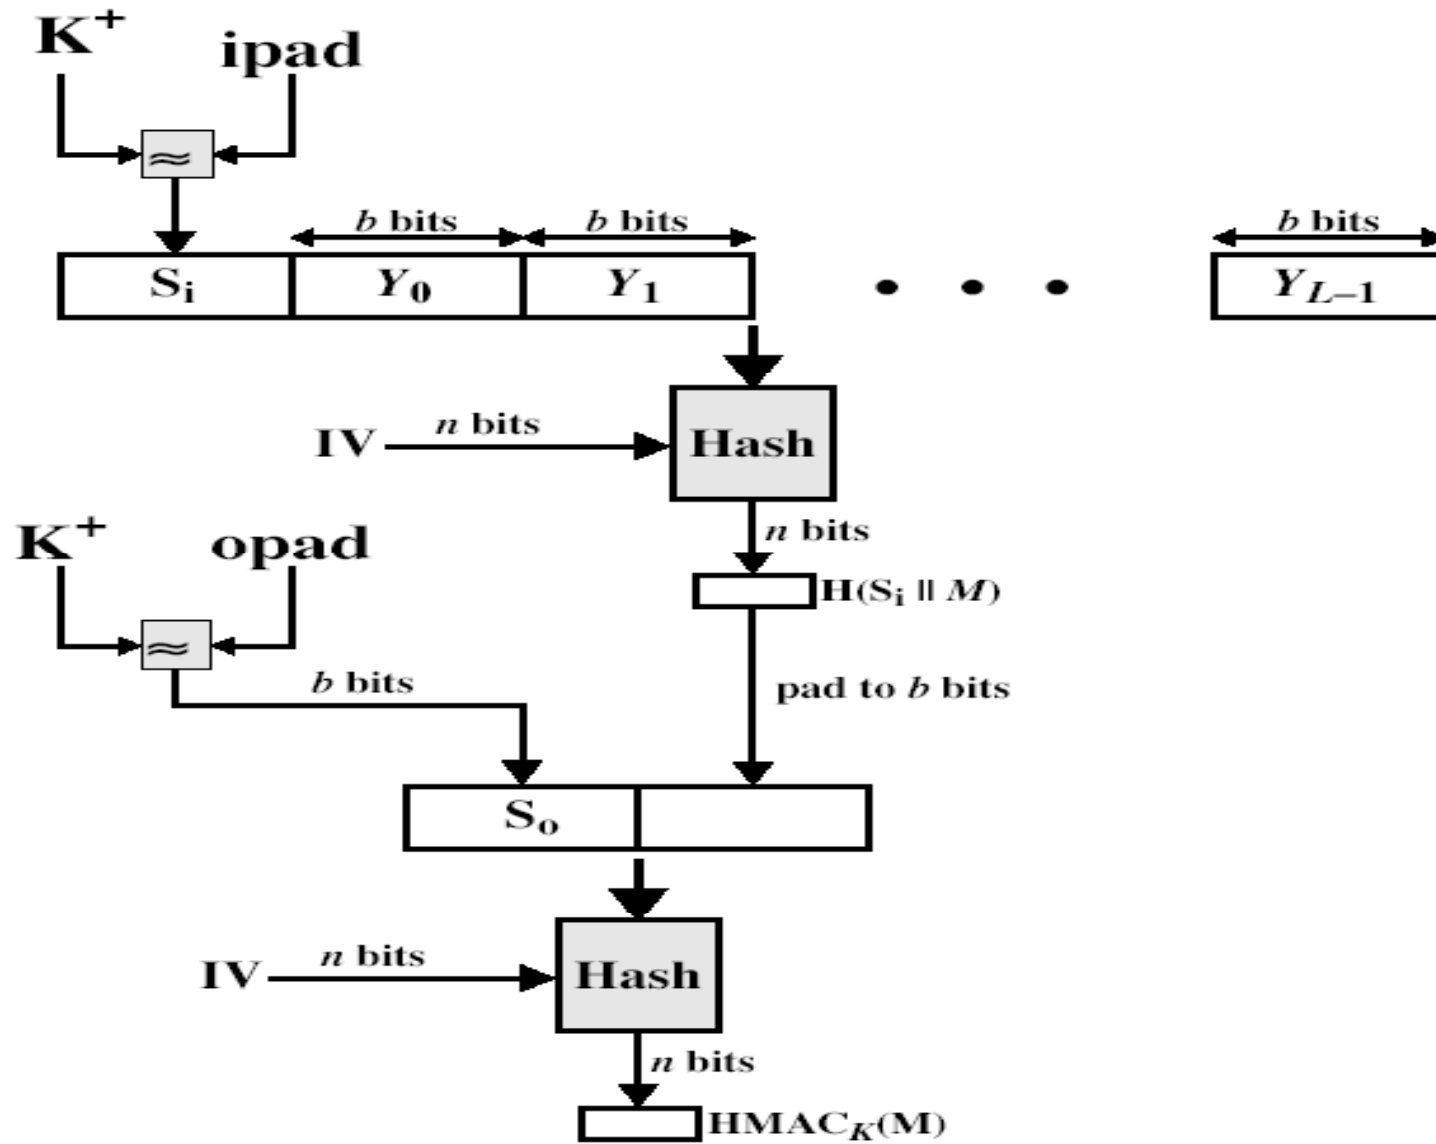

- Let  $h$  be a one-way hash function
- $H(K,M) = h(K \parallel M)$ , where  $\parallel$  denote concatenation
  - Insecure as MAC
  - Given  $M$  and  $a=h(K \parallel M)$ , can compute  $M'=M\parallel\dots$  and  $a'$ , such that  $h(K\parallel M') = a'$
- $H(K,M) = h(M \parallel M)$ ,
  - Also insecure as MAC

# HMAC: Constructing MAC from Cryptographic Hash Functions

$$\text{HMAC}_K[M] = \text{Hash}[(K^+ \oplus \text{opad}) \parallel \text{Hash}[(K^+ \oplus \text{ipad}) \parallel M]]$$

- $K^+$  is the key padded (with 0) to B bytes, the input block size of the hash function
- $\text{ipad}$  = the byte 0x36 repeated B times
- $\text{opad}$  = the byte 0x5C repeated B times.

# HMAC Overview

# HMAC Security

- If used with a secure hash functions (e.g., SHA-256) and according to the specification (key size, and use correct output), no known practical attacks against HMAC

# Encryption and Authentication

- Three ways for encryption and authentication
  - Authenticate-then-encrypt (AtE), used in SSL
    - $a = \text{MAC}(x)$ ,  $C = E(x, a)$ , transmit  $C$
  - Encrypt-then-authenticate (EtA), used in IPSec
    - $C = E(x)$ ,  $a = \text{MAC}(C)$ , transmit  $(C, a)$
  - Encrypt-and-authenticate (E&A), used in SSH
    - $C = E(x)$ ,  $a = \text{MAC}(x)$ , transmit  $(C, a)$
- Which way provides secure communications when embedded in a protocol that runs in a real adversarial network setting?

# Encryption Alone May Be Insufficient for Privacy

- If an adversary can manipulate a ciphertext such that the observable behavior (such as success or failure of decryption) differs depending on the content of plaintext, then information about plaintext can be leaked
- To defend against these, should authenticate ciphertext, and only decrypt after making sure ciphertext has not changed
- Encrypt-then-authenticate (EtA) is secure
  - $C=E(x)$ ,  $a=MAC(C)$ , transmit  $(C,a)$

# Encryption Alone May Be Insufficient for Privacy: An Artificial Example

- Given a secure stream cipher (or even one-time pad)  $E$ , Consider encryption  $E^*$ 
  - $E^*[x] = E[\text{encode}[x]]$ 
    - $\text{encode}[x]$  replaces 0 with 00, and 1 with either 01 or 10.
  - How to decrypt?
  - $E^*[x]$  is secure
- Using  $E^*$  may not provide confidentiality in some usage
  - Consider the case an adversary flips the first two bits of  $E^*[x]$
  - When the bits are 01 or 10, flipping results in no change after decrypt
  - When the bits are 00, flipping result in decryption failure
  - Learning whether decryption succeeds reveal first bit

# AtE and E&A are insecure

- Authenticate-then-encrypt (AtE) is not always secure
  - $a = \text{MAC}(x)$ ,  $C = E(x, a)$ , transmit  $C$
  - As first step is decryption, its success or failure may leak information.
  - AtE, however, can be secure for some encryption schemes, such as CBC or OTP (or stream ciphers)
- Encrypt-and-authenticate (E&A) is not secure
  - $C = E(x)$ ,  $a = \text{MAC}(x)$ , transmit  $(C, a)$
  - MAC has no guarantee for confidentiality

# Readings for This Lecture

- Wikipedia
  - Message Authentication Code
- Optional reading
  - Hugo Krawzyck.: "The Order of Encryption and Authentication for Protecting Communications"

# Coming Attractions ...

- Operating System Security Basics
