

TCP connection establishment (3-way handshake):

- X, Y are chosen randomly
→ sequence number prediction
- piggybacking

2-person consensus problem: are A and B in agreement about the state of affairs after 3-way handshake?

- in general: impossible
- can be proven
- “acknowledging the ACK problem”
- also TCP session ending
- lunch date problem

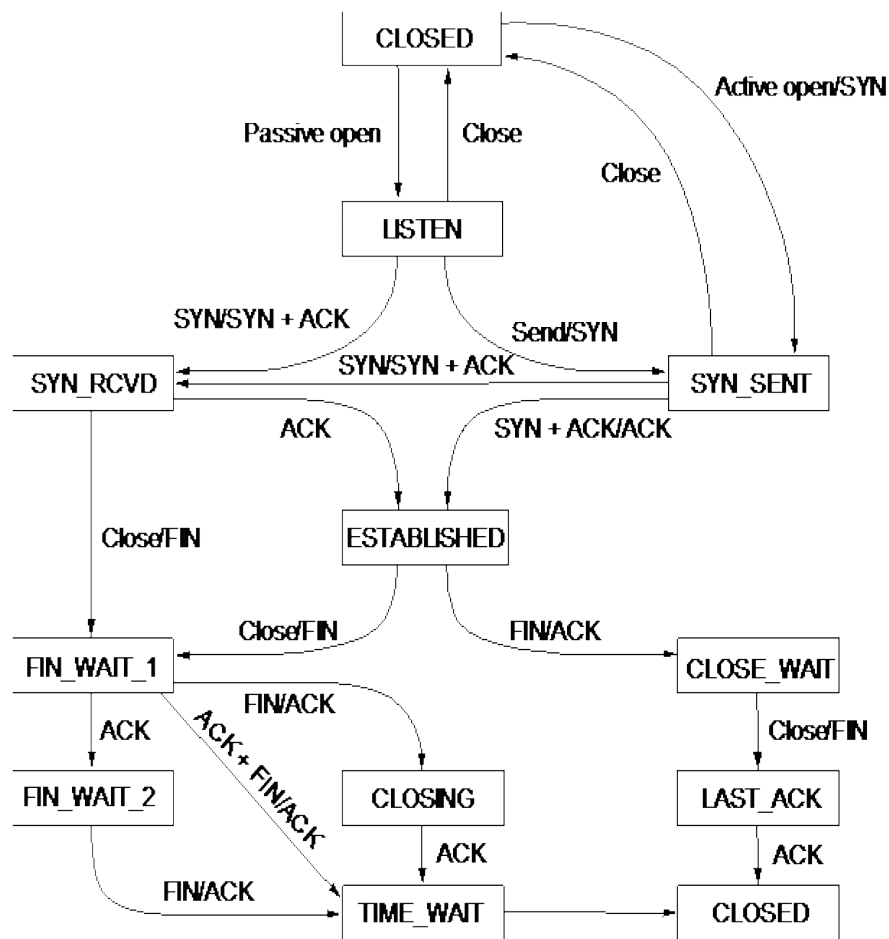

TCP connection termination:

- full duplex
- half duplex

More generally, finite state machine representation of TCP's control mechanism:

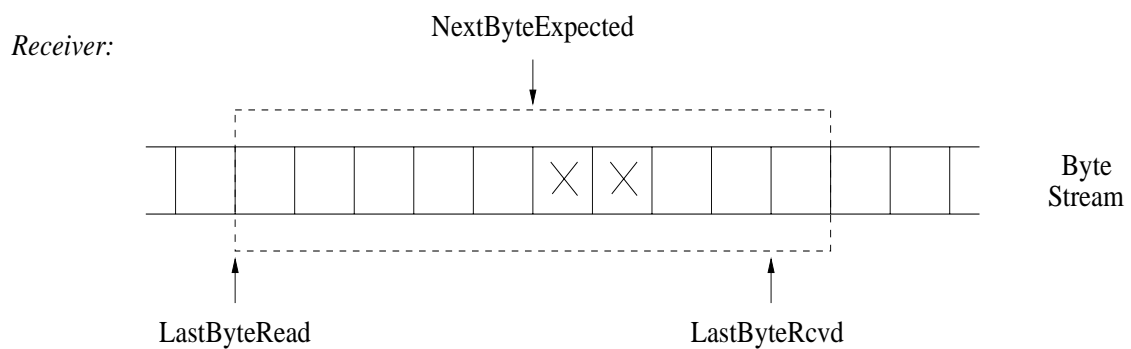

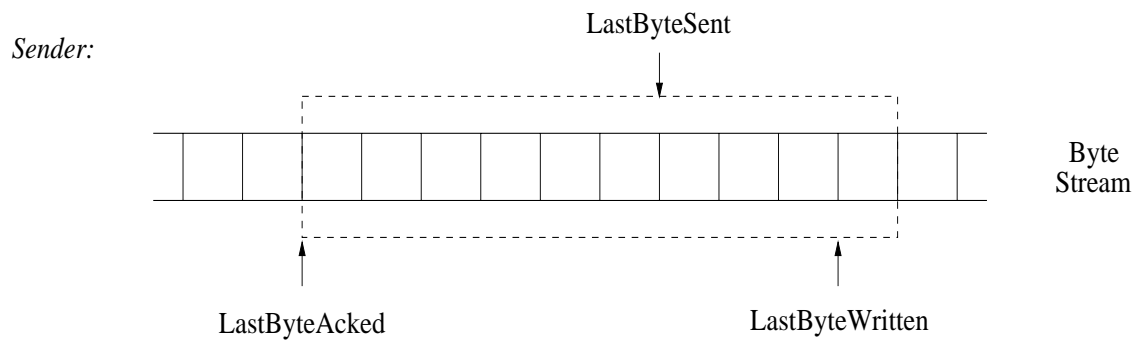

→ state transition diagram

Features to notice:

- Connection set-up:
 - client's transition to **ESTABLISHED** state without **ACK**
 - how is server to reach **ESTABLISHED** if client **ACK** is lost?
 - **ESTABLISHED** is macrostate (partial diagram)
- Connection tear-down:
 - three normal cases
 - special issue with **TIME WAIT** state
 - employs hack

TCP's sliding window protocol

- sender, receiver maintain buffers `MaxSendBuffer`, `MaxRcvBuffer`

Same as generic sliding window

→ data unit: byte, not packet

Sender side: maintain invariants

- $\text{LastByteAcked} \leq \text{LastByteSent} \leq \text{LastByteWritten}$
- $\text{LastByteWritten} - \text{LastByteAcked} < \text{MaxSendBuffer}$

→ buffer flushing (advance window)

→ application blocking

- $\text{LastByteSent} - \text{LastByteAcked} \leq \text{AdvertisedWindow}$

→ **AdvertisedWindow**: receiver side free space

→ throttling effect

How much sender can still send:

$$\text{EffectiveWindow} = \text{AdvertisedWindow} - (\text{LastByteSent} - \text{LastByteAcked})$$

- upper bound
- sender may choose to send less
- self-throttling

Affected through sender side variable

- `CongestionWindow`

EffectiveWindow update procedure:

$$\text{EffectiveWindow} = \text{MaxWindow} - (\text{LastByteSent} - \text{LastByteAcked})$$

where

$$\text{MaxWindow} = \min\{\text{AdvertisedWindow}, \text{CongestionWindow}\}$$

How to set CongestionWindow.

→ TCP congestion control

Receiver side: maintain invariants

- $\text{LastByteRead} < \text{NextByteExpected} \leq \text{LastByteRcvd} + 1$
- $\text{LastByteRcvd} - \text{NextByteRead} < \text{MaxRcvBuffer}$
 - buffer flushing (advance window)
 - application blocking

Thus,

$$\text{AdvertisedWindow} = \text{MaxRcvBuffer} - (\text{LastByteRcvd} - \text{LastByteRead})$$

Issues:

How to let sender know of change in receiver window size after `AdvertisedWindow` becomes 0?

- trigger ACK event on receiver side when `AdvertisedWindow` becomes positive
- sender periodically sends 1-byte probing packet
 - design choice: smart sender/dumb receiver
 - same situation for congestion control

Silly window syndrome: Assuming receiver buffer is full, what if application reads one byte at a time with long pauses?

- can cause excessive 1-byte traffic
- if `AdvertisedWindow < MSS` then set
`AdvertisedWindow ← 0`

Do not want to send too many 1 B payload packets.

Nagle's method:

- rule: connection can have only one such unacknowledged packet outstanding
- while waiting for ACK, incoming bytes are accumulated (i.e., buffered)

... compromise between real-time constraints and efficiency.

→ useful for **telnet/ssh**-type interactive applications

RTT estimation

... important to not underestimate nor overestimate.

Karn/Partridge: Maintain running average with precautions

$$\text{EstimateRTT} \leftarrow \alpha \cdot \text{EstimateRTT} + \beta \cdot \text{SampleRTT}$$

- **SampleRTT** computed by sender using timer

- $\alpha + \beta = 1$; $0.8 \leq \alpha \leq 0.9$, $0.1 \leq \beta \leq 0.2$

- **TimeOut** $\leftarrow 2 \cdot \text{EstimateRTT}$ or

TimeOut $\leftarrow 2 \cdot \text{TimeOut}$ (if retransmit)

→ need to be careful when taking **SampleRTT**

→ infusion of complexity

→ still remaining problems

Hypothetical RTT distribution:

→ need to account for variance

→ not nearly as nice

Jacobson/Karels:

- $\text{Difference} = \text{SampleRTT} - \text{EstimatedRTT}$
- $\text{EstimatedRTT} = \text{EstimatedRTT} + \delta \cdot \text{Difference}$
- $\text{Deviation} = \text{Deviation} + \delta(|\text{Difference}| - \text{Deviation})$

Here $0 < \delta < 1$.

Finally,

- $\text{TimeOut} = \mu \cdot \text{EstimatedRTT} + \phi \cdot \text{Deviation}$

where $\mu = 1$, $\phi = 4$.

→ persistence timer

→ how to keep multiple timers in UNIX
