Abstract. Tries (from retrieval) are one of the most popular data structures on words. They are pertinent to the (internal) structure of stored words and several splitting procedures used in diverse contexts. The profile of a trie is a parameter that represents the number of nodes (either internal or external) with the same distance from the root. It is a function of the number of strings stored in a trie and the distance from the root. Several, if not all, trie parameters such as height, size, depth, shortest path, and fill-up level can be uniformly analyzed through the (external and internal) profiles. Although profiles represent one of the most fundamental parameters of tries, they have hardly been studied in the past. The analysis of profiles is surprisingly arduous, but once it is carried out it reveals unusually intriguing and interesting behavior. We present a detailed study of the distribution of the profiles in a trie built over random strings generated by a memoryless source. We first derive recurrences satisfied by the expected profiles and solve them asymptotically for all possible ranges of the distance from the root. It appears that profiles of tries exhibit several fascinating phenomena. When moving from the root to the leaves of a trie, the growth of the expected profiles varies. Near the root, the external profiles tend to zero at an exponential rate, and then the rate gradually rises to being logarithmic; the external profiles then abruptly tend to infinity, first logarithmically and then polynomially; they then tend polynomially to zero again. Furthermore, the expected profiles of asymmetric tries are oscillating in a range where profiles grow polynomially, while symmetric tries are nonoscillating, in contrast to most shape parameters of random tries studied previously. Such a periodic behavior for asymmetric tries implies that the depth satisfies a central limit theorem but not a local limit theorem of the usual form. Also the widest levels in symmetric tries contain a linear number of nodes, differing from the order \( n/\sqrt{\log n} \) for asymmetric tries, \( n \) being the size of the trees. Finally, it is observed that profiles satisfy central limit theorems when the variance goes unbounded, while near the height they are distributed according to Poisson laws. As a consequence of these results we find typical behaviors of the height, shortest path, fill-up level, and depth. These results are derived here by methods of analytic algorithmics such as generating functions, Mellin transform, Poissonization and de-Poissonization, the saddle-point method, singularity analysis, and uniform asymptotic analysis.

1. Introduction. Tries are prototype data structures useful for many indexing and retrieval purposes. They were first proposed by de la Briandais [9] in the late 1950s for information processing; Fredkin [27] suggested the current name as it is
part of retrieval. Tries are multiway trees whose nodes are vectors of characters or digits. Due to their simplicity and efficiency, tries found widespread use in diverse applications including document taxonomy, IP address lookup, data compression, dynamic hashing, partial-match queries, speech recognition, leader election algorithms, and distributed hashing tables (see [29, 50, 53, 79]). In this paper, we are concerned with probabilistic properties of the profiles of tries, where the profile of a tree is the sequence of numbers each corresponding to the number of nodes with the same distance from the root. We discover several new phenomena in the profiles of tries built over strings generated by a random memoryless source, and develop asymptotic tools to describe them.

**Structure and usefulness of tries.** Tries are a natural choice of data structure when the input records involve a notion of alphabets or digits. They are often used to store such data so that future retrieval can be made efficient. Given a sequence of \( n \) words over the alphabet \( \{a_1, \ldots, a_m\} \), \( m \geq 2 \), we can construct a trie as follows. If \( n = 0 \), then the trie is empty. If \( n = 1 \), then a single (external) node holding the word is allocated. If \( n \geq 1 \), then the trie consists of a root (internal) node directing words to the \( m \) subtrees according to the first alphabet of each word, and words directed to the same subtree are themselves tries (see [50, 53, 79] for more details). For simplicity, we deal only with binary tries in this paper. Unlike other search trees such as digital search trees and binary search trees where records or keys are stored at the internal nodes, the internal nodes in tries are branching nodes used merely to direct records to each subtree, with all records stored in external nodes that are leaves of such tries. A trie has more internal nodes than external nodes (fixed to be \( n \) throughout this paper), differing from almost all other search trees. In Figure 1 we plot a binary trie of five strings.

The simple organizing procedure used to construct tries and the general efficiency they achieve make tries one of the most popular digital search trees. Since their invention, tries have found frequent use in many computer science applications. For example, tries are widely used in algorithms for automatically correcting words in texts (see [51]) and in algorithms for taxonomies and toolkits of regular language (see the Ph.D. thesis [80]); they are also used to represent the event history in datarace detection for multithreaded object-oriented programs (see [6]); another example is the Internet IP address lookup problem (see [60, 74]), where the search time for the IP address problem is directly related to the distribution of the fill-up level (see below for a more precise definition) and other trie parameters. For applications to other problems in searching, sorting, dynamic hashing, coding, polynomial factorization, Lempel–Ziv compression schemes, and molecular biology, see [29, 79].

The structure of tries also has a close connection to several splitting procedures using coin-flipping; these include algorithms for resolving collisions in multiaccess (or broadcast) communication models, algorithms for loser selection or leader election, etc.; see [45]. Thus most shape parameters in tries have direct interpretations in terms of other related objects.

**Random tries under the Bernoulli model.** Throughout the paper, we write \( B_{n,k} \) to denote the number of external nodes (leaves) at distance \( k \) from the root; the number of internal nodes at distance \( k \) from the root is denoted by \( I_{n,k} \). For simplicity, we will refer to \( B_{n,k} \) as the external profile and \( I_{n,k} \) as the internal profile. Figure 1 shows a trie and its profiles.

In this paper we study the profiles of a trie built over \( n \) binary strings generated by a memoryless source. More precisely, we assume that the input is a sequence of \( n \) independent and identically distributed random variables, each being composed of an
infinite sequence of Bernoulli random variables with mean $p$, where $0 < p < 1$ is the probability of a “1” and $q := 1 - p$ is the probability of a “0.” The corresponding trie constructed from these $n$ binary strings is called a random trie. This simple model may seem too idealized for practical purposes; however, the typical behaviors under such a model often hold under more general models such as Markovian or dynamical sources, although the technicalities are usually more involved (see, for example, [8, 12, 15, 35]).

The motivation of studying the profiles is multifold. First, they are fine shape measures closely connected to many other cost measures on tries; some of them are indicated below. Second, they are also asymptotically close to the profiles of suffix trees, which in turn have a direct combinatorial interpretation in terms of words; see [36, 59, 78, 79] for more information and another interpretation in terms of urn models. Third, not only are the analytic problems mathematically challenging, but the diverse new phenomena they exhibit are highly interesting and unusual. Fourth, our findings imply several new results on other shape parameters (see section 8). Finally, most properties of random tries have also a prototype character and are expected to hold for other varieties of digital search trees (and under more general random models), although the proofs are generally more complicated.

**Major cost measures on random tries.** Due to the usefulness of tries, many cost measures, discussed below, on random tries have been studied in the literature since the early 1970s, and most of these measures can be expressed and analyzed through the profiles studied in this paper:

- **depth**: the distance from the root to a randomly selected node; its distribution is given by the expected external profile divided by $n$; see [10, 12, 13, 20, 24, 33, 36, 42, 46, 52, 65, 71, 75, 76];
- **total path length**: the sum of distances between nodes and the root, or, equivalently, $\sum_j jI_{n,j}$; see [8, 11, 24, 44, 58, 57, 70, 71, 72, 73, 75];
- **size**: the total number of internal nodes, or $\sum_j I_{n,j}$; see [8, 24, 34, 36, 40, 41, 43, 47, 50, 57, 67, 68, 69, 70, 71, 72, 73];
- **height**: the length of the longest path from the root, or $\max\{j : B_{n,j} > 0\}$; see [8, 11, 12, 13, 14, 22, 26, 33, 48, 64, 65, 77];
- **shortest path**: the length of the shortest path from the root to an external node, or $\min\{j : B_{n,j} > 0\}$; see [64, 65];
• **fill-up (or saturation) level**: the largest full level, or max\( \{ j : I_{n,j} = 2^j \} \), where the levels of a tree denote the sets of nodes with the same distance from the root; see [49];

• **Horton–Strahler number and stack-size**: certain notions of heights related to the traversal of tries; see [4, 17, 54, 55, 56];

• **distance of two randomly chosen nodes**: see [1, 7];

• **pattern occurrences in tries (including page usage or b-tries)**: see [22, 42, 43, 58, 71, 76];

• **one-sided height (or leader election or loser selection)**: see [21, 39, 66, 81, 82].

The reader is referred to the book [79] and the papers [15, 37, 71] for a systematic treatment of several of these quantities.

**The general analytic context.** The major difference between most previous study and the current paper is that we are dealing with the asymptotics of bivariate recurrence, in contrast to univariate recurrences (with or without maximization or minimization) addressed in the literature.

To be more precise, we observe that, by assumption of the model, the probability generating function

\[
P_{n,k}(y) := E(y^{B_{n,k}})
\]

satisfies the recurrence

\[
P_{n,k}(y) = \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j} P_{j,k-1}(y) P_{n-j,k-1}(y) \quad (n \geq 2; \ k \geq 1)
\]

with the initial conditions \( P_{n,k}(y) = 1 + \delta_{n,1} \delta_{k,0} (y - 1) \) when either \( n \leq 1 \) and \( k \geq 0 \) or \( k = 0 \) and \( n \geq 0 \), where \( \delta_{a,b} \) is the Kronecker symbol. Observe that this recurrence depends on two parameters \( n \) and \( k \), which makes the analysis quite challenging, as we will demonstrate in this paper. The probability generating functions of the internal profile satisfy the same recurrence (1) but with different initial conditions; see section 6.

From (1), the moments of \( B_{n,k} \) and \( I_{n,k} \) (centered or not) are seen to satisfy a recurrence of the form

\[
x_{n,k} = a_{n,k} + \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j} (x_{j,k-1} + x_{n-j,k-1})
\]

with suitable initial conditions, where \( a_{n,k} \) are known (either explicitly or inductively). A standard approach is to consider the Poisson generating function \( \tilde{f}_k(z) := e^{-z} \sum_n x_{n,k} z^n / n! \), which in turn satisfies the functional equation

\[
\tilde{f}_k(z) = \tilde{g}_k(z) + \tilde{f}_{k-1}(pz) + \tilde{f}_{k-1}(qz)
\]

with a suitable \( \tilde{g}_k(z) \). This equation can be solved explicitly by a simple iteration argument and asymptotically by using the Mellin transform (see [23, 79]). The final step is to invert from the asymptotics of the Poisson generating function \( \tilde{f}_k(z) \) to recover the asymptotics of \( x_{n,k} \). This last step is guided by the **Poisson heuristic**, which roughly states that

\[
x_n \sim y_n \text{ if } \lim_{n \to \infty} x_n / y_n = 1.
\]

Such a Poisson heuristic has appeared in diverse contexts under different forms such as Borel summability and Tauberian theorems; it dates back at least to Ramanujan’s Notebooks; see the book by Berndt [3, pp. 57–66] for more details. It is known as **analytic de-Poissonization** when justified...
by complex analysis and the saddle-point method, and was the subject of intensive
analysis, resulting in a robust solution presented in [37].

By means of the Poisson heuristic (2), we expect that \( \mu_{n,k} \sim e^{-n} \sum_{j \geq 0} \mu_{j,k} n^j / j! \). However, as we will see, such a heuristic holds in our case when \( q^{2k} n \to 0 \) but fails otherwise. The reason is that \( \mu_{n,k} \) is too small in this range. Also it should be
mentioned that the asymptotic analysis of the above functional equation is in general
more intricate because we have an additional parameter \( k \) to be taken into account
and we need uniformity for our asymptotic approximations in \( k \) (varying with \( n \)) and
in \( z \) (in some region in the complex plane) in order to invert the results to obtain \( x_{n,k} \)
by suitable complex analysis.

**Known results for profiles.** As far as probabilistic properties of the profiles of ran-
dom tries are concerned, very little is known in the literature. Since the distribution of
the depth, \( D \), is close to the height. Devroye [14] showed that \( E \) if

\[
\mu_{n,k} = \frac{B_{n,k}}{\sqrt{n}} \quad \text{if} \quad \frac{\mathbb{E}(B_{n,k})}{\sqrt{n}} \to \infty, \quad \text{then} \quad \frac{B_{n,k}}{\mathbb{E}(B_{n,k})} \to 1 \quad \text{in probability};
\]

\[
\text{if} \quad \mathbb{E}(I_{n,k}) \to \infty, \quad \text{then} \quad \frac{I_{n,k}}{\mathbb{E}(I_{n,k})} \to 1 \quad \text{in probability},
\]

under very general assumptions on the underlying models (see also [15] for further
refinements). References [65] and [14] represent known results concerning profiles. We
will see that convergence in probability in the two “if statements” holds as long as
the variance tends to infinity.

**Sketch of the major phenomena.** In the next section we present an in-depth dis-
cussion of our results. Here, we briefly summarize our main findings. We focus
mostly on the profiles of asymmetric tries (when \( p \neq q \)) since the symmetric tries
(varying with \( n \)) and

\[
\log(1 - \epsilon) \log n / \log(n/q) \quad \text{the average profile}
\]

\( \mu_{n,k} \) is exponentially small where \( \epsilon > 0 \) is small. When \( k \) increases and lies in the
range \( (\log n - \log \log \log n + O(1))/\log(n/q) \), then \( \mu_{n,k} \) decays to zero logarithmically
until \( k > k^* \) for a specific threshold \( k^* \) in this range beyond which \( \mu_{n,k} \) suddenly
grows unbounded at a logarithmic rate. The rate becomes polynomial \( \Theta(n^v) \) for
some \( 0 < v \leq 1 \) when

\[
\frac{1}{\log(1/q)}(1 + \epsilon) \log n \leq k \leq \frac{2}{\log(1/(p^2 + q^2))}(1 - \epsilon) \log n.
\]

Surprisingly enough, for this range of \( k \) an oscillating factor emerges in the expected
profile behavior; that is, \( \mathbb{E}(B_{n,k}) \approx G(\log(p/q) n^v)\sqrt{\log n} \), where \( G \) is a bounded
periodic function. Such behavior is a consequence of an infinite number of saddle-
points appearing in the integrand of the associated Mellin integral transform. This
was first observed by Nicodème [59]. For larger values of $k$, these oscillations disappear since the behavior of the expected profile is dominated by a polar singularity.

Analogous results also hold for the internal profile. In addition, we prove that the variances of both profiles are asymptotically of the same order as their expected values. This suggests a central limit theorem for both external and internal profiles for a wide range of $k$. We show that this is indeed true; furthermore, we also show that for $k$ near the height the limiting distribution of the profiles becomes Poisson. Some of these results were already anticipated in [63] and constitute the Ph.D. thesis of the first author [62].

Profiles of digital and nondigital log trees. In passing, we observe that most random trees in the discrete probability literature fall into two major categories according to their expected height being of order $\sqrt{n}$ (referred to as square-root trees for brevity) or of order $\log n$ (referred to as log trees), where $n$ is the tree size. While most random square-root trees were introduced in combinatorics and probability, the majority of log trees arise from data structures and computer algorithms.

We can further classify log trees into “digital-type” and “nondigital-type” log trees, according to the nature of construction (or search) of the tree. Profiles of nondigital-type search trees of logarithmic height for which binary search trees are representative have received much recent attention and are shown to exhibit several interesting phenomena such as bimodality of the variance and multifaceted behaviors of the limiting distributions; see [5, 18, 19, 28, 31] for more information. In contrast, profiles of digital-type search trees have not been addressed as much, and most properties remain unknown; see [14, 15, 65] for tries and [2, 38] for digital search trees. We will show that the limiting behaviors of the profiles are very different from those of nondigital search trees. In particular, while in no range will the normalized profiles in random binary search trees lead to asymptotic normality (in the sense of convergence in distribution), profiles of random tries, when properly centered and normalized, all converge to the standard normal law when the variance goes unbounded in the limit. As is often the case for proving asymptotic normality, we need more precise asymptotic approximation to the variance, rendering our analysis more complicated.

Organization of the paper. The paper is organized as follows. In the next section, we present (rather informally) a more detailed summary of our main findings. This section is to help the reader to comprehend the richness of our results in their fullness but without resorting to rather abstruse mathematical formulations. Sections 3–8 are devoted to precise formulations of our results. This paper contains two major parts: The first, section 3, develops the asymptotic tools we need for deriving the diverse asymptotic approximations to the expected external profile $\mu_{n,k}$. Most proofs of the second part (sections 4–8) are then sketched because they extend the same methods of proof as in the first part. Except for sections 7 and 8, we assume $p \neq q$ throughout this paper. Among these sections, section 4 derives the asymptotics of the variance of $B_{n,k}$, the corresponding results of convergence in distribution being given in section 5. The internal profiles are addressed in section 6, and results for symmetric tries are given in section 7. Consequences of our findings are discussed in section 8, where we establish typical behaviors of the height, the width, the shortest path, the fill-up level, and the right-profile, as well as a rather atypical local limit theorem for the depth.

2. Summary of main results. In this section we discuss informally our main results. We focus here on describing the major phenomena arising in the analysis of
profiles rather than presenting the precise and complicated results to which we devote the remaining sections of this paper.

Crucial to our analysis of the profiles is the asymptotics of the expected profiles. Not only are the results fundamental and highly interesting, but the analytic methods we used are also of certain generality.

From (1), we see that the expected external profile \( \mu_{n,k} := \mathbb{E}(B_{n,k}) \) satisfies the following recurrence:

\[
\mu_{n,k} = \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j}(\mu_{j,k-1} + \mu_{n-j,k-1})
\]

for \( n \geq 2 \) and \( k \geq 1 \) with the initial values \( \mu_{n,0} = 0 \) for all \( n \neq 1 \) and 1 for \( n = 1 \). Furthermore, \( \mu_{0,k} = 0 \), \( k \geq 0 \), and \( \mu_{1,k} = 0 \) for \( k \geq 1 \) and is equal to 1 when \( k = 0 \). Throughout we assume that \( p > q = 1 - p \) unless stated otherwise.

The polynomial growth of \( \mu_{n,k} \). In section 3, we solve asymptotically (3) for various ranges of \( k \) when \( p \neq q \); a crude description of the asymptotics of \( \mu_{n,k} \) is as follows:

\[
\log \frac{\mu_{n,k}}{\log n} \rightarrow \begin{cases} 
0 & \text{if } \alpha \leq \alpha_1, \\
-\rho + \alpha \log(p^{-\rho} + q^{-\rho}) & \text{if } \alpha_1 \leq \alpha \leq \alpha_2, \\
2 + \alpha \log(p^2 + q^2) & \text{if } \alpha_2 \leq \alpha \leq \alpha_3, \\
0 & \text{if } \alpha \geq \alpha_3,
\end{cases}
\]

where

\[
\alpha_1 := \frac{1}{\log(1/q)}, \quad \alpha_2 := \frac{p^2 + q^2}{p^2 \log(1/p) + q^2 \log(1/q)}, \quad \text{and} \quad \alpha_3 := \frac{2}{\log(1/(p^2 + q^2))}
\]

are delimiters of \( \alpha := \lim_n k/\log n \) (\( k = k(n) \)), and

\[
\rho := \frac{1}{\log(p/q)} \log \left( \frac{1 - \alpha \log(1/p)}{\alpha \log(1/q) - 1} \right).
\]

Note that \( \alpha_1 \leq \alpha_2 \); see Figure 2. The limiting estimate (4) gives a rough picture of \( \mu_{n,k} \) as follows: \( \mu_{n,k} \) is of polynomial growth rate when \( \alpha_1 + \varepsilon \leq \alpha \leq \alpha_3 - \varepsilon \) and is smaller than any polynomial powers when \( 0 \leq \alpha \leq \alpha_1 - \varepsilon \) and \( \alpha \geq \alpha_3 + \varepsilon \). Near the two boundaries \( \alpha_1 \) and \( \alpha_3 \), the behaviors of \( \mu_{n,k} \) will undergo phase changes from being subpolynomial to being polynomial or the other way around.

More refined asymptotics. To derive more precise asymptotics of \( \mu_{n,k} \) than the phase transitions (4) of the polynomial order of \( \mu_{n,k} \), we divide all possible values of \( k \) into four overlapping ranges.

(I) Elementary range: \( 1 \leq k \leq \alpha_1 (\log n - \log \log n + O(1)) \).

(II) Saddle-point range: \( \alpha_1 (\log n - \log \log n + K_n) \leq k \leq \alpha_2 (\log n - K_n \sqrt{\log n}) \).

(III) Gaussian transitional range: \( k = \alpha_2 \log n + o(\log n)^{2/3} \).

(IV) Polar singularity range: \( k \geq \alpha_2 \log n + K_n \sqrt{\log n} \).

where, throughout this paper, \( K_n \geq 1 \) represents a (generic) sequence tending to infinity.

More precisely, in Theorem 1 we prove that for \( k \) lying in range (I) the expected external profile \( \mu_{n,k} \) first decays exponentially fast (asymptotic to \( q^k n(1 - q^k)^{n-1} \)).
Then, when $k$ is around $\alpha_1 (\log n - \log \log n + \log (p/q - 1) + m \log(p/q))$ for some integer $m \geq 0$,

$$\mu_{n,k} \sim \frac{k^m}{m!} p^m q^{k-m} n e^{-np^m q^{k-m}},$$

which is of order

$$\mu_{n,k} = O \left( \frac{\log \log n}{(\log n)^{\xi-m}} \right)$$

for some $\xi$. Thus, for $m < \xi$ the expected external profile decays only logarithmically, but for $m \geq \xi$ it increases logarithmically.

The behavior of $\mu_{n,k}$ in range (II) is described in Theorem 2. The situation becomes highly nontrivial and interesting. More precisely, for $\alpha_1 (1 + \varepsilon) \log n \leq k \leq \alpha_2 (1 - \varepsilon) \log n$, we find that

$$\mu_{n,k} \sim G_1 \left( \rho; \log_{p/q} p^k n \right) \frac{p^\rho q^\rho (p^{-\rho} + q^{-\rho})}{\sqrt{2\pi n \alpha_{n,k} \log(p/q)}} \frac{n^{\nu_1}}{\sqrt{\log n}},$$

where $(\alpha_{n,k} := k/\log n)$

$$\nu_1 = -\rho + \alpha_{n,k} \log(p^{-\rho} + q^{-\rho}),$$

$$\rho = -\frac{1}{\log(p/q)} \log \left( \frac{-1 - \alpha_{n,k} \log q}{1 + \alpha_{n,k} \log p} \right),$$

and $G_1(\rho; x)$ is a periodic function. We plot in Figures 3 and 4 the periodic parts of $G_1(-1, x)$ for a few values of $p$ and $\rho$, respectively. Analytically, these oscillations are consequences of an infinite number of saddle-points appearing in the integrand of the associated Mellin transform of the expected profile, but visually they look like certain sine waves due to the fact that the corresponding Fourier expansions involve a
Gamma function with increasing parameters, which decreases very fast along a fixed vertical line for an increasing imaginary part, so that only a few terms dominate. Finally, in Theorem 3 we prove that for $k$ in range (IV)

$$\mu_{n,k} \sim \frac{2pqn^2(p^2 + q^2)^{k-1}}{p^2 + q^2} n^\nu_2,$$

where $\nu_2 = 2 + \alpha_{n,k} \log(p^2 + q^2)$, and the periodic function disappears. In this region, the asymptotic behavior of the expected profile is dictated by the expected number of pairs (of input-strings) having common prefixes of length at least $k$. This property is analytically reflected by a polar singularity in the associated Mellin transform. The asymptotics of $\mu_{n,k}$ in range (III) for $k = \alpha_2 \log n + o(\log^{2/3} n)$ are presented in Theorem 4. In this transitional range, the saddle-point coalesces with the polar singularity, so we use the Gaussian integral to describe the behavior of $\mu_{n,k}$.

In summary, our results roughly state that $\mu_{n,k} \to 0$ when $1 \leq k \leq k^*$ for some $k^*$ close to $\alpha_1(\log n - \log \log \log n + O(1))$, and then $\mu_{n,k}$ tends abruptly to infinity at a logarithmic rate when $k > k^*$. Such an abrupt change has already been observed in the literature for the shortest path and the fill-up level (see [49, 65]), but not much is known for $\mu_{n,k}$ beyond that. Then we show that $\mu_{n,k}$ grows polynomially when $k$ lies in the range $\alpha_2(1 + \varepsilon) \log n \leq k \leq \alpha_3(1 - \varepsilon) \log n$, reaching the peak where it is of order $n/\sqrt{\log n}$; it decays at a slower rate afterwards until it tends to zero again when $k \geq \alpha_3(\log n + K_n)$. A salient feature here is the presence of an oscillating function in the asymptotic approximation when $p \neq q$.\(^1\) In Figure 5, a plot of the rough silhouettes of $\mu_{n,k}$ is presented.

\(^1\)The expected values of many shape characteristics of random tries often exhibit the asymptotic pattern: $\sim F(\log n, n)$ if $\log p/\log q$ is rational for some periodic function $F$ and constant $c$ expressible in terms of $p$, and $\sim Cn$ if $\log p/\log q$ is irrational; see [37, 71, 79].
Asymptotics of the expected internal profile. The expected value of the internal profile $E(I_{n,k})$ is discussed in section 6. In particular, the expected internal profile is asymptotically equivalent to $2^k$ for $k \leq \alpha_0 (\log n - K_n \sqrt{\log n})$, where $\alpha_0 := 2 / (\log(1/p) + \log(1/q))$. When $k \geq \alpha_2 (\log n + K_n \sqrt{\log n})$, then $E(I_{n,k}) \sim (p^2 + q^2)E(B_{n,k})/pq$. Between these two ranges, it is again the infinite number of saddle-points that yield the dominant asymptotic approximation. Unlike $\mu_{n,k}$, an additional phase transition appears in the asymptotics of the $E(I_{n,k})$ when $k = \alpha_0 \log n + O(\sqrt{\log n})$, reflecting the structural change of the internal nodes from being asymptotically full to being of the same order as the number of external nodes. The silhouettes of the expected internal profiles for a symmetric trie and an asymmetric ($p = 0.75$) trie are presented in Figure 6.

Variance and limiting distributions. In section 4 we deal with the variance of the profile. In particular, in Theorem 7 we derive asymptotic approximations to the variance of the profile, which asymptotically turns out to be of the same order as the expected value for all ranges of $k \geq 1$; namely, $V(B_{n,k}) = \Theta(E(B_{n,k}))$. In fact, we show that $V(B_{n,k}) \sim E(B_{n,k})$ in range (I), for range (IV) $V(B_{n,k}) \sim 2E(B_{n,k})$, and in range (II) (polynomial growth) the variance and the expected profile differ only by the oscillating functions. The variance of the internal profile behaves almost identically to the variance of the external profile; roughly, $V(I_{n,k}) = \Theta(V(B_{n,k}))$ for all $k$. The methods used to derive these results are the same as those used in section 3.

We then prove, in section 5, that both internal and external profiles, after proper normalization, are asymptotically normally distributed iff the variance tends to infinity (see Theorems 8 and 9). The limiting distribution is Poisson when the variance
remains bounded away from zero and infinity. In particular, we will prove that when $\mathbb{V}(B_{n,k}) = \Theta(1)$,

$$\mathbb{P}(B_{n,k} = 2m) = \frac{\lambda_0^m}{m!} e^{-\lambda_0} + o(1) \quad \text{and} \quad \mathbb{P}(B_{n,k} = 2m + 1) = o(1),$$

where $\lambda_0 := pqn^2(p^2 + q^2)^{k-1}$, while for $\mathbb{V}(I_{n,k}) = \Theta(1)$, we find

$$\mathbb{P}(I_{n,k} = m) = \frac{\lambda_1^m}{m!} e^{-\lambda_1} + o(1) \quad (m = 0, 1, \ldots),$$

where $\lambda_1 := n^2(p^2 + q^2)^k/2$. These results hold for both symmetric and asymmetric tries, but the ranges where the variances become unbounded are different.

**Symmetric tries.** For the symmetric case, we have $\alpha_1 = \alpha_2 = 1/\log 2$. This means that the two ranges separated by $\alpha_2$ coalesce into one for symmetric tries; see Figure 2. The analysis then becomes simpler as shown in section 7. An interesting property is that unlike for asymmetric tries, the fattest levels of profiles of symmetric tries contain a linear number of nodes. The global picture of a random symmetric trie is roughly as follows ($\alpha_1 = 1/\log 2$):

- When $1 \leq k \leq \alpha_1(\log n - \log \log n + O((\log n)^{-1}))$, each level is almost full of internal nodes ($I_{n,k} \approx 2^k$), the number of external nodes tending to zero; in particular, the variances of both profiles tend to zero.
- When $\alpha_1(\log n - \log \log n + K_n/\log n) \leq k \leq 2\alpha_1(\log n - K_n)$, where $K_n$ is any sequence tending to infinity, the variances of both profiles tend to infinity, and we prove the asymptotic normality of both profiles.
- When $k = 2\alpha_1(\log n + O(1))$, both profiles are asymptotically Poisson distributed, but $B_{n,k}$ assumes only even values.
- When $k \geq \alpha_1(\log n + K_n)$, then nodes appear very unlikely.

Section 8 describes some consequences of our main results. In particular, we point out a rather unusual form of the local limit theorem for the depth due to the oscillating factor in the expected profile. Then we apply our results to rederive typical behavior for the height, the shortest path, and the fill-up level. Also, the width and

![Fig. 6. The silhouettes of the expected external and internal profiles of a symmetric; compare Figure 5.](image-url)
the right-profile (counting only right right branches and neglecting the left ones) are briefly discussed.

This completes the summary of our main results. Precise formulations and proofs are presented in the next five sections. Enjoy the reading!

3. Expected external profile. We derive asymptotic approximations to the expected external profile $\mu_{n,k}$ in this section, starting with a few useful expressions for $\mu_{n,k}$.

Notation. Throughout this paper, $p \in [1/2, 1)$ is fixed and $q = 1 - p$. Let $k = k(n)$ and $\alpha := \lim k / \log n$, whenever the limit exists. The constants $\alpha_1, \alpha_2$, and $\alpha_3$ are defined in (5). For convenience, we also write

$$L_n := \log n, \quad LL_n := \log \log n, \quad LLL_n := \log \log \log n.$$ 

The generic symbol $\varepsilon$ is always used to represent a suitably small constant whose value may vary from one occurrence to another, and $K_n$ denotes any sequence tending to infinity. The symbol $f(n) = \Theta(g(n))$ means that there are positive constants $C$ and $C'$ such that $C|g(n)| \leq |f(n)| \leq C'|g(n)|$.

3.1. Exact expressions and integral representations. Denote by $M_k(z)$ the probability generating function $\sum_{n \geq 0} \mu_{n,k} z^n / n!$ of $\mu_{n,k}$ and by $\tilde{M}_k(z)$ the corresponding Poisson generating function $\tilde{M}_k(z) := e^{-z} M_k(z)$.

LEMMA 1. The Poisson generating function $\tilde{M}_k(z)$ satisfies the integral representation

$$\tilde{M}_k(z) = \frac{1}{2\pi i} \int_{(\rho)} z^{-s} \Gamma(s + 1) g(s) \left( p^{-s} + q^{-s} \right)^{k} ds$$
for $k \geq 1$ and $\Re(z) > 0$, where $\Gamma$ denotes the Gamma function, $g(s) := 1 / (p^{-s} + q^{-s})$, and $\int_{(\rho)}$ stands for the integral $\int_{\rho-i\infty}^{\rho+i\infty}$. The integral with $\rho > -2$ is absolutely convergent for $\Re(z) > 0$.

Proof. By taking the derivative with respect to $y$ on both sides of (1) and then substituting $y = 1$, we see that $\mu_{n,k}$ satisfies the recurrence (3) with the initial conditions $\mu_{n,k} = \delta_{n,1} \delta_{k,0}$ when either $n \leq 1$ and $k \geq 0$ or $k = 0$ and $n \geq 0$. Note that

$$\mu_{n,1} = n \left( pq^{n-1} + qp^{n-1} \right) \quad (n \geq 2).$$

It follows that

$$M_k(z) = e^{qz} M_{k-1}(pz) + e^{pz} M_{k-1}(qz) \quad (k \geq 2),$$
with $M_1(z) = z (pe^{qz} + qe^{pz} - 1)$. Thus $\tilde{M}_k(z)$ satisfies

$$\tilde{M}_k(z) = \tilde{M}_{k-1}(pz) + \tilde{M}_{k-1}(qz).$$

Iterating this equation yields

$$\tilde{M}_k(z) = \sum_{0 \leq j < k} \binom{k-1}{j} M_1(p^j q^{k-1-j} z),$$
from which (6) follows since the Mellin transform

$$M_1^*(s) = \int_0^\infty z^{s-1} M_1(z) dz.$$

of $\tilde{M}_1(z) = pze^{-pz} + qze^{-qz} - ze^{-z}$ equals

$$M_1(s) = \Gamma(s+1)(p^{-s} + q^{-s} - 1),$$

where $\Re(s) > -2$, and the Mellin transform of $M_1(p^j q^{k-1-j} z)$ is $p^{-sj}q^{-s(k-1-j)} M_1(s)$ (see [23, 79]).

To justify the absolute convergence of the integral, we apply the Stirling formula for the Gamma function (with complex parameter)

$$\Gamma(s+1) = \sqrt{2\pi s} \left(\frac{s}{e}\right)^s \left(1 + O(|s|^{-1})\right),$$

uniformly as $|s| \to \infty$ and $|\arg s| \leq \pi - \varepsilon$, which implies that

$$\Gamma(\rho + it) = \Theta(|t|^{\rho-1/2} e^{-\pi|t|/2}),$$

uniformly for $|t| \to \infty$ and $\rho = o(|t|^{2/3})$.

The integrand in (6) is analytic for $\Re(s) > -2$ and bounded above by

$$z^{-\rho-it} \Gamma(\rho + it) g(\rho + it) (p^{-\rho-it} + q^{-\rho-it})^k$$

$$= O \left(|z|^{-\rho}|t|^{\rho+1/2} e^{-\pi|t|/2 + \arg|z|} (p^{-\rho} + q^{-\rho})^k\right)$$

for large $|t|$. This completes the proof of the lemma.

**Corollary 1.** The expected external profile $\mu_{n,k}$ satisfies, for $n, k \geq 1$,

$$\mu_{n,k} = \sum_{0 \leq j < k} \binom{k}{j} p^j q^{k-j} n (1 - p^j q^{k-j})^{n-1}$$

$$- \sum_{0 \leq j < k} \binom{k-1}{j} p^j q^{k-1-j} n (1 - p^j q^{k-1-j})^{n-1}$$

and the integral representation

$$\mu_{n,k} = \frac{1}{2\pi i} \int_{(\rho)} \frac{\Gamma(n+1)\Gamma(s+1)}{\Gamma(n+1+s)} g(s) (p^{-s} + q^{-s})^k ds \quad (\rho > -2),$$

where $g(s) = 1 - 1/(p^{-s} + q^{-s})$.

**Proof.** By definition and (8)

$$M_k(z) = \sum_{0 \leq j < k} \binom{k-1}{j} p^j q^{k-1-j} \left(p e^{(1-p^{j+1} q^{k-1-j}) z} + q e^{(1-p^{j+1} q^{k-1-j}) z} - e^{(1-p^j q^{k-1-j}) z}\right).$$

Thus (the symbol $[z^n] f(z)$ denoting the coefficient of $z^n$ in the Taylor expansion of $f(z)$),

$$\mu_{n,k} = n! \left[z^n\right] M_k(z)$$

$$= \sum_{0 \leq j < k} \binom{k-1}{j} \left(p^{j+1} q^{k-1-j} n (1 - p^{j+1} q^{k-1-j})^{n-1} + p^j q^{k-j} n (1 - p^j q^{k-j})^{n-1}\right)$$

$$- \sum_{0 \leq j < k} \binom{k-1}{j} p^j q^{k-1-j} n (1 - p^j q^{k-1-j})^{n-1}.$$
Rearranging the indices of the first sum, we obtain (10).

On the other hand, it also follows from (7) that, denoting by \( \bar{\mu}_{n,k} := n! [z^n] \tilde{M}_k(z) \),

\[
\bar{\mu}_{n,k} = (p^n + q^n) \bar{\mu}_{n,k-1} \quad (k \geq 2),
\]

with

\[
\bar{\mu}_{n,1} = \sum_{2 \leq j \leq n} \binom{n}{j} (-1)^{n-j} \mu_{j,1} = (-1)^n n (1 - p^n - q^n) \quad (n \geq 1).
\]

Iterating this recurrence yields

\[
\bar{\mu}_{n,k} = (-1)^n n (1 - p^n - q^n) (p^n + q^n)^{k-1} \quad (n, k \geq 1).
\]

By definition, we have for \( n \geq 2 \)

\[
\mu_{n,k} = \sum_{0 \leq j \leq n} \binom{n}{j} \bar{\mu}_{j,k} = \sum_{2 \leq j \leq n} \binom{n}{j} (-1)^j j (1 - p^j - q^j) (p^j + q^j)^{k-1}.
\]

The last sum falls under the so-called Rice integral representation for finite differences (see [25, 79]) from which we conclude

\[
\mu_{n,k} = \frac{1}{2\pi i} \int_{(\rho)} \frac{\Gamma(n+1)\Gamma(-s)}{\Gamma(n+1-s)} s (1 - p^s - q^s) (p^s + q^s)^{k-1} ds.
\]

This gives (11). Absolute convergence of the integral in (11) when \( \Re(s) > -2 \) is justified as above. Note that \( g(-1) = 0 \).

Remarks. The integral representation (11) follows formally from interchanging the Cauchy and Mellin integrals as shown below:

\[
\mu_{n,k} = \frac{n!}{2\pi i} \int z^{-n-1} e^z \tilde{M}_k(z) dz
\]

\[
= \frac{n!}{2\pi i} \int z^{-n-1} e^z \left( \frac{1}{2\pi i} \int z^{-s} \Gamma(s+1) g(s) (p^{-s} + q^{-s})^k dz \right) ds
\]

\[
= \frac{n!}{2\pi i} \Gamma(s+1) g(s) \left( \frac{1}{2\pi i} \int z^{-n-1-s} e^z dz \right) ds
\]

\[
= \frac{n!}{2\pi i} \frac{\Gamma(s+1)}{\Gamma(n+s+1)} g(s) (p^{-s} + q^{-s})^k ds.
\]

Although all steps here can be justified by analytic properties of the functions involved (which are essentially the estimates needed by the saddle-point method), the way we proved (11), based solely on finite differences, does not rely on any analytic properties.

Note that since the Mellin transform of \( x(1-x)^{n-1}, x \in (0,1) \), equals \( \Gamma(n) \Gamma(s+1)/\Gamma(n+1+s) \), the exact expression (10) also follows from (11) by expanding \( (p^{-s} + q^{-s})^k \) and then integrating term by term. For numerical purposes, the expression (10) is preferable to (12), especially when \( k \) is not too large.

On the other hand, the closed-form expression (10) can also be proved directly by either a direct combinatorial argument (see [65] for similar details) or an urn model argument (see [59]).
3.2. Road map of the proof through de-Poissonization. From the preceding analysis, we have a choice of two different integral representations: the Rice integral (11) and the Cauchy integral (13). The approach via the Rice integral (11) is simpler than that via the Cauchy and Mellin integrals (13), but the latter can be easily amended for computing the variance and limiting distribution as will be evident from sections 4 and 5. It is for this reason that we use here the route via the Cauchy and Mellin integrals.

By the Poisson heuristic (2), we anticipate the asymptotic equivalence \( \mu_{n,k} \sim \tilde{M}_k(n) \). We will see that this holds when \( q^{2k} n \to 0 \) but requires suitable modification when \( q^{2k} n \neq 0 \).

A simple analytic de-Poissonization result. Define a sequence of (Charlier) polynomials \( \tau_\ell(n) \) by

\[
\tau_\ell(n) := n!\left[z^n e^z (z-n)\right]^\ell = \ell!\left[z^n\right](1+z)^n e^{-nz} \quad (\ell = 0, 1, \ldots).
\]

Then \( \tau_0(n) = 1, \tau_1(n) = 0, \tau_2(n) = -n, \tau_3(n) = 2n, \) and \( \tau_4(n) = 3n^2 - 6n \). Note that \( \tau_\ell(n) \) is a polynomial in \( n \) of degree \( |\ell/2| \).

**Proposition 1.** Let \( f(z) := \sum a_n z^n/n! \) be an entire function, where \( a_n \) is a given sequence, and let \( \tilde{f}(z) := e^{-z} f(z) \). Write \( z = re^{i\theta} \). If

\[
|f(z)| \leq f(r) e^{-cr\theta^2}
\]

holds uniformly for \( r \geq 0, c > 0, \) and \( |\theta| \leq \pi, \) where \( f(r) \geq 0 \), and

\[
\tilde{f}(\ell)(ne^{i\theta}) = O\left(\delta(n)\ell^\ell \tilde{f}(n)\right) \quad (\ell = 0, 1, \ldots)
\]

holds uniformly for \( |\theta| \leq \theta_1 \), where \( \theta_1 \geq n^{-1/2+\varepsilon} \) and \( \delta(n) = o(n^{-1/2}) \), then for any \( \ell_0 \geq 2 \)

\[
a_n = \sum_{0 \leq \ell < \ell_0} \frac{\tilde{f}(\ell)(n)}{\ell!} \tau_{\ell}(n) + O\left(n^{\ell_0/2} \delta(n)^{\ell_0} \tilde{f}(n)\right).
\]

**Proof.** By the Cauchy formula and the condition (14), we have

\[
a_n = \frac{n!}{2\pi i} \int_{|z|=n} \frac{z^{-n-1} e^z \tilde{f}(z)dz}{\left|\arg(z)\right| \leq \theta_0} + O\left(n!n^{-n} f(n) \int_{\theta_0}^{\infty} e^{-cn\theta^2} d\theta\right),
\]

where \( \theta_0 = n^{-2/5} \). By Stirling’s formula, we see that the \( O \)-term in (17) is bounded above by

\[
O\left(n^{1/2} \tilde{f}(n)n^{-1/2} e^{-cn^{1/5}}\right) = O\left(e^{-cn^{1/5}} \tilde{f}(n)\right),
\]

which is negligible in comparison to the main term \( \tilde{f}(n) \). It remains to evaluate the first term in (17). To that purpose, we expand \( \tilde{f}(z) \) at \( z = n \) and then integrate term by term, the error term introduced being of the form

\[
\frac{n!}{2\pi i (\ell_0 - 1)!} \int_{|z|=n} \frac{z^{-n-1} e^z (z-n)^{\ell_0} dz}{\left|\arg(z)\right| \leq n^{-2/5}} \int_0^1 (1-t)^{\ell_0-1} \tilde{f}(\ell_0)(n+(z-n)t) dtdz,
\]
for any \( \ell_0 \geq 1 \), which is easily seen, by (15), to be bounded above by the \( O \)-term in (16); see [30] for similar details. Since \( \delta(n) = o(n^{-1/2}) \), this proves the asymptotic nature of (16).

Remark: In particular, we have
\[
a(n) = \bar{f}(n) + O(n\delta^2(n)\bar{f}(n)),
\]
(19)
\[
a(n) = \bar{f}(n) - \frac{n}{2} \bar{f}''(n) + O\left(n^2\delta^4(n)\bar{f}(n)\right)
\]
for large \( n \).

The theorem indicates that, when the regularity condition (14) and the smoothness condition (15) both hold for \( \tilde{\mu}(z) \), the asymptotics of \( \mu_{n,k} \) are reduced to those of their Poisson generating function \( \tilde{M}_k(z) \) for large \( z \) near the real axis. Our effort in this section is mostly devoted to finding the uniform bounds for justifying the de-Poissonization result (16), which holds for \( \mu_{n,k} \) when \( q^{2k}n \to 0 \). Note that although the condition (14) may seem too strong for our purposes, it can be checked rather systematically in the cases studied in this paper; see [37] for weaker conditions.

On the other hand, we show that when (16) fails (which is the case when \( q^{2k}n \to 0 \)), the same proof given above through the Cauchy integral (17) can be appropriately amended because (18) also holds in this case. Thus when deriving our asymptotic estimates for \( \mu_{n,k} \), we will either follow the de-Poissonization route through Proposition 1 or evaluate the integral (13) directly using (17).

3.3. Range (I): An elementary analysis. We show in this section that when
\[ 1 \leq k \leq \alpha_1(L_n - LLL_n + O(1)) \]
the asymptotics of \( \mu_{n,k} \) are dictated by one or two terms in the first sum of (10). Although the asymptotics of \( \mu_{n,k} \) in this range can be easily derived by (10) using only elementary arguments, we will use a lengthier analytic approach based on Cauchy’s integral representation since this approach is readily amended later for the asymptotics of the variance. Define
\[
k_m := \alpha_1 \left( L_n - LLL_n + \log \left( \frac{p}{q} - 1 \right) + m \log \frac{p}{q} \right) \quad (m \geq 0),
\]
(20)
\[
S_{n,k,j} := \binom{k}{j} p^j q^{k-j} n (1 - p^j q^{k-j})^{n-1} \quad (0 \leq j \leq k).
\]
For convenience, define \( k_{-1} = 0 \).

Our first result says that \( \mu_{n,k} \) is asymptotic to \( S_{n,k,m} \) when \( k_{m-1} < k < k_m \) except when \( k \) is close to the boundaries, where the corresponding neighboring term (either \( S_{n,k,m-1} \) or \( S_{n,k,m+1} \)) is of the same order.

**Theorem 1** (asymptotics of \( \mu_{n,k} \) in range (I)). Assume \( m \geq 0 \). If
\[
k_{m-1} + \frac{\alpha_1 K_n}{LLL_n} \leq k \leq k_m - \frac{\alpha_1 K_n}{LLL_n},
\]
then
\[
\mu_{n,k} = S_{n,k,m} \left( 1 + O((m + 1)e^{-K_n}) \right).
\]
If \( k = k_m + \alpha_1 x/LLL_n \), where \( x = o(\sqrt{LLL_n}) \), then
\[
\mu_{n,k} = S_{n,k,m} \left( 1 + \frac{p\alpha_1 x}{\bar{q}(m + 1)} \right) \left( 1 + O \left( x^2 LLL_n^{-1} + (m + 1)L_n^{1-q/p} \right) \right).
\]

(23)
Remark. Since \( \log(p/q) < 1 \) for \( p \in (1/2, e/(e+1)) \), the interval (21) may contain no integer.

By Theorem 1, the proofs of the following special cases are straightforward.

**Corollary 2.** If \( k \geq 1 \) and \( q^k n \to \infty \), then
\[
\mu_{n,k} \sim q^k n (1 - q^k)^{n-1};
\]
if \( q^k n \to 0 \) and \( k \leq \alpha_1 (L_n - LLL_n + K_n) \), then
\[
S_{n,k,m} \sim \frac{k^m}{m!} p^m q^{k-m} e^{-p^m q^{k-m}} \quad (m \geq 0).
\]

On the other hand, the estimate
\begin{equation}
(24) \quad \mu_{n,k} = \Theta(S_{n,k,m})
\end{equation}
holds uniformly for \( k_{m-1} \leq k \leq k_m \), \( m \geq 0 \).

The proof of Theorem 1 is based on evaluating the Cauchy integral (13) along the circle \( |z| = n \) by the same arguments used in the proof of Proposition 1 (see (18)). Observe that
\begin{equation}
(25) \quad \mu_{n,k} = \frac{n!}{2\pi i} \int_{|z|=n} z^{-n-1} e^z M_k(z) dz + O \left(e^{-cn^{1/4}} M_k(n)\right),
\end{equation}
where the \( O \)-term is justified by applying the following estimate for \( M_k(z) \).

**Lemma 2.** Uniformly for \( r \geq 0 \) and \( |\theta| \leq \pi \)
\begin{equation}
(26) \quad |M_k(re^{i\theta})| \leq M_k(r) e^{-cr^2} \quad (r > 0; |\theta| \leq \pi)
\end{equation}
for all \( k = k(n) \geq 1 \) and some constant \( c > 0 \).

The proof of (26) follows directly from the next proposition in view of (8) and \( [z^n] M_k(z) \geq 0 \).

**Proposition 2.** Let \( f(z) \) be an entire function and let \( z = re^{i\theta} \), where \( r \geq 0 \) and \( |\theta| \leq \pi \). If
\begin{equation}
(27) \quad |e^z f(z)| \leq e^r f(r) \quad (r \geq 0; |\theta| \leq \pi),
\end{equation}
where \( f(r) \geq 0 \), then the sum \( f_k(z) := \sum_{0 \leq j \leq k} \binom{k}{j} f(p^j q^{k-j} z) \) satisfies
\begin{equation}
(28) \quad |e^z f_k(z)| \leq e^{r f_k(r)} e^{-cr^2},
\end{equation}
uniformly for \( k \geq 0 \), \( r \geq 0 \), and \( |\theta| \leq \pi \), where \( c > 0 \) is independent of \( z \) and \( k \).

**Proof.** By (27) and the elementary inequality
\begin{equation}
(29) \quad 1 - \cos \theta \geq \frac{2}{\pi^2} \theta^2 \quad (|\theta| \leq \pi),
\end{equation}
we obtain
\[
|e^z f_k(z)| \leq \sum_{0 \leq j \leq k} \binom{k}{j} e^{(1-p^j q^{k-j})r} e^{p^j q^{k-j}} \frac{r f(p^j q^{k-j} r)}{r f_k(r)}
\leq \sum_{0 \leq j \leq k} \binom{k}{j} e^{(1-p^j q^{k-j})r(1-2\theta^2/\pi^2)} e^{p^j q^{k-j}} r f(p^j q^{k-j} r)
\leq e^{-2r^2 \theta^2 (1-p^k)/\pi^2} e^r f_k(r).
\]
This proves (28) with, say, \( c = 2(1-p)/\pi^2 \).
Proof of (22) in Theorem 1. We next evaluate $\tilde{M}_k(z)$ more precisely in the following lemma whose proof is presented in Appendix A.

Let

$$S_{k,m}(z) := \binom{k-1}{m} p^m q^{k-m} z e^{-p^m q^{k-m} z}.$$

**Lemma 3.** (i) $(m = 0)$. If $1 \leq k \leq k_0 - \alpha_1 K_n / LL_n$, then

$$\tilde{M}_k(z) = q^k z e^{-q^k z} \left(1 + O(e^{-K_n})\right),$$

uniformly for $|z| = n$ and $\arg(z) = o(LL_n^{-1/2}).$

(ii) $(m \geq 1)$. If

$$k = \alpha_1 (L_n - LLP_n + \log(p/q - 1) + m \log(p/q) - \eta),$$

where $m \geq 1$ and

$$\frac{K_n}{LL_n} \leq \eta \leq \log(p/q) - \frac{K_n}{LL_n},$$

then

$$\tilde{M}_k(z) = S_{k,m}(z) \left(1 + O(me^{-K_n})\right),$$

uniformly for $|z| = n$ and $\arg(z) = o(LL_n^{-1/2}).$

Using the above lemma, we now prove Theorem 1. It remains to evaluate the integral in (25). We first consider the case $m = 0$. By substituting (30) into the integral in (25), and by completing the arc $|\arg(z)| \leq \theta_0$ to a full circle, we see that

$$\frac{n!}{2\pi i} \int_{|z|=n} z^{-n-1} e^z \tilde{M}_k(z) dz = \frac{q^k n!}{2\pi i} \int_{|z|=n} z^{-n} e^{(1-q^k)z} dz + O(E_1)$$

$$= q^k \frac{n!}{2\pi i} \int_{\theta_0}^{\theta_0} e^{(1-q^k)\theta} d\theta + O(E_2) + O(E_1),$$

where

$$E_1 := e^{-K_n} n! n^{-1} q^k \int_{-\theta_0}^{\theta_0} e^{(1-q^k)\theta} \cos \theta d\theta,$$

$$E_2 := q^k n! n^{-1} \int_{\theta_0}^{\pi} e^{(1-q^k)\theta} \cos \theta d\theta.$$

By inequality (29), we have

$$E_1 = O \left(e^{-K_n} n^{1/2} q^k n e^{-q^k n} \int_{-\infty}^{\infty} e^{-2n(1-q^k)\theta^2/\pi^2} d\theta \right)$$

$$= O \left(e^{-K_n} q^k n e^{-q^k n} \right).$$

Similarly,

$$E_2 = O \left(q^k n e^{-q^k n} n^{-1/10} e^{-2n^{1/5}/\pi^2} \right).$$

This completes the proof of (22) when $m = 0$. For $m \geq 1$, we proceed in a similar manner but using part (ii) of Lemma 3.
Proof of (23) in Theorem 1. We now consider the remaining gaps when \( k \) is of the form (31) with \( \eta = x/\sqrt{L_n} \), where \( x = o(\sqrt{L_n}) \). In this case, the same analysis as above shows that both terms \( S_{k,m}(z) \) and \( S_{k,m+1}(z) \) are asymptotically close so that

\[
(33) \quad \tilde{M}_k(z) = (S_{k,m}(z) + S_{k,m+1}(z))(1 + O(E_3)),
\]

where the error \( E_3 \) introduced is bounded above by

\[
E_3 = O \left( \sum_{0 \leq j < m} \left| \frac{S_{k,j}(z)}{S_{k,m}(z)} \right| + \sum_{m+2 \leq j \leq k} \left| \frac{S_{k,j}(z)}{S_{k,m}(z)} \right| \right)
\]

\[
= O \left( (m+1)L_n^{-\frac{1}{2}}e^\theta \right) + O \left( m! \sum_{j \geq 2} \frac{(p \alpha_1/q)^j}{j!} L_n^{-\frac{j}{p+q}} e^\theta \right)
\]

\[
= O \left( (m+1)L_n^{-\frac{1}{2}} + (m+1)^{-1}L_n^{-\frac{1}{p-1}} \right)
\]

\[
= O \left( (m+1)L_n^{-\frac{1}{p-1}} \right),
\]

since \( 1 - q/p \leq p/q - 1 \), where we used the inequality

\[
\frac{t^j - 1}{t - 1} \geq \frac{t + 1}{2} j \quad (t > 1; \ j \geq 2),
\]

and \( \theta = o(\sqrt{L_n^{-1/2}}) \). Thus the same analysis as above gives

\[
\mu_{n,k} = \frac{k^m}{m!} p^m q^{k-m} n^{e^{-p}q^{-m}n} \left( 1 + \frac{pL_n^{1-e^\theta}}{q(m+1)\log(1/q)} \right) \left( 1 + O \left( (m+1)L_n^{-\frac{1}{p-1}} \right) \right),
\]

which implies (23).  \( \square \)

3.4. Range (II): A saddle-point analysis. We now assume that

\[
(34) \quad \alpha_1 \left( L_n - 3LL_n + K \right) \leq k \leq \alpha_2 \left( L_n - \sqrt{L_n} \right),
\]

and proceed by the saddle-point method (see [79, 83]) to derive the following main result of this subsection.

Theorem 2 (asymptotics of \( \mu_{n,k} \) in range (II)). If \( k \) satisfies (34), then

\[
(35) \quad \mu_{n,k} = G_1 \left( \rho, \log(p/q), p^{k/n} \right) \left( \frac{n^{-\rho}(p^{-\rho} + q^{-\rho})^k}{\sqrt{2\pi\beta_2(\rho)^{1/2}}} \right) \left( 1 + O \left( \frac{1}{k(p/q)^{\rho} + \frac{1}{k(\rho + 2)^2}} \right) \right),
\]

where \( \rho = \rho(n,k) > -2 \) is chosen to satisfy the saddle-point equation

\[
\left\{ \begin{align*}
\frac{d}{d\rho} \left( \rho^\rho e^{-\rho}n^{-\rho}(p^{-\rho} + q^{-\rho})^k \right) &= 0 & \text{if } \rho \geq 1, \\
\frac{d}{d\rho} \left( n^{-\rho}(p^{-\rho} + q^{-\rho})^k \right) &= 0 & \text{if } \rho \leq 1,
\end{align*} \right.
\]

and

\[
(37) \quad \beta_2(\rho) := \left( \frac{p^{-\rho}q^{-\rho}\log(p/q)^2}{(p^{-\rho} + q^{-\rho})^2} \right),
\]

\[G_1(\rho;x) = \sum_{j \in \mathbb{Z}} g(\rho + it_j)\Gamma(\rho + 1 + it_j)e^{-2j\pi x} \quad (t_j := 2j\pi/\log(p/q))\]
with $g(s) = 1 - 1/(p^{-s} + q^{-s})$, and $G_1(\rho, x)$ is a 1-periodic function (see Figures 3 and 4).

We devote the rest of this subsection to the proof of Theorem 2.

3.4.1. Two-step saddle-point method. Here we outline the main steps of the proof of Theorem 2. The approach may be called a two-step saddle-point method since the saddle-point method will be applied twice. First, we start from the Mellin integral (6) and apply the saddle-point method to obtain precise asymptotics of $\tilde{M}_k(\beta re^{i\theta})$ for small $\theta$ (i.e., around the real axis) and large $r$. The proof here is complicated by the fact that

$$|p^{-\rho-it} + q^{-\rho-it}| = p^{-\rho} + q^{-\rho}$$

when $t = t_j = 2\pi j / \log(p/q)$, $j \in \mathbb{Z}$, which implies that the number of saddle-points with the same real part is infinite, yielding the 1-periodic function $G_1(\rho; x)$.

This first application of the saddle-point method yields a good approximation to $\tilde{M}_k(z)$ for $z$ large and near the real axis; then we de-Poissonize $\tilde{M}_k(z)$ by another application of the saddle-point method and establish that $\mu_{n,k} \sim \tilde{M}_k(n)$. Ultimately, we will use the de-Poissonization result of Proposition 1; however, in the first approximation we do de-Poissonization by “bare hands” by applying the argument already used in the proof of Proposition 1, namely, (17) and (18). Thus we focus on the evaluation of the Cauchy integral (13) but with $|\theta| \leq n^{-2/5}$ (the first integral of (25)).

3.4.2. Location of saddle-points. The integrand $z^{-s}\Gamma(s+1)g(s)(p^{-s} + q^{-s})^k$ of the integral in (6) has simple poles at $s = -j$, $j = 2, 3, \ldots, k$; it also has saddle-points, which are the zeros of the equation

$$\frac{d}{ds} \left( \Gamma(s+1)n^{-s}(p^{-s} + q^{-s})^k \right) = 0$$

(note that $g(s)$ is uniformly bounded for all $s$). In view of (38), there are infinitely many saddle-points of the form $\rho + it_j / \log(p/q) \ (j = 0, \pm 1, \ldots)$, where the real part $\rho$ satisfies (39). Also it is easy to see that

$$\begin{cases} \rho \to +\infty & \text{if } \frac{k}{\log(1/p)} < \frac{1}{\log(1/q)} \\ \rho \to -\infty & \text{if } \frac{k}{\log(1/p)} > \frac{1}{\log(1/q)} \end{cases}$$

We distinguish between two cases $\rho \geq 1$ and $-2 < \rho < 1$. In the former, the saddle-points are asymptotically determined, by Stirling’s formula for the Gamma function, by the first equation in (36), which is simpler than (39), while in the latter case they are asymptotically determined by the second equation of (36) since $\Gamma(\rho+1)$ is uniformly bounded and thus does not contribute significantly to the saddle-point location.

More precisely, first consider the case when $\rho \geq 1$ (the choice of 1 being arbitrary). In this case, by (36), we obtain

$$\frac{k}{L_n - \log \rho} = \frac{p^{-\rho} + q^{-\rho}}{p^{-\rho} \log(1/p) + q^{-\rho} \log(1/q)}$$

which can be written in the form

$$\rho = \frac{1}{\log(p/q)} \log \left( \frac{L_n - \log \rho - k \log(1/p)}{k \log(1/q) - L_n + \log \rho} \right)$$
whenever \( L_n - \log \rho < k \log(1/q) \), which will be seen to be the case when \( k \) satisfies (34).

On the other hand, when \( \rho \leq 1 \), we consider the second equation in (36) or

\[
\frac{k}{L_n} = \frac{p^{-\rho} + q^{-\rho}}{p^{-\rho} \log(1/p) + q^{-\rho} \log(1/q)},
\]

which is solved to be

\[
\rho = \frac{1}{\log(p/q)} \log \left( \frac{L_n - k \log(1/p)}{k \log(1/q) - L_n} \right). \tag{40}
\]

It follows that if \( k \) satisfies (34), then

\[
\rho \leq \frac{1}{\log(p/q)} \left( L - \log K + \log \left( \frac{\log(p/q)}{\log(1/q)} \right) + o(1) \right), \tag{41}
\]

implying, in particular, that \( \rho = O(L) \). Also, if \( k = \alpha_1 (L_n - KL_n + \log(p/q) + K_n) \), then

\[
\rho = \frac{1}{\log(p/q)} \left( L - \log K + \log \left( \frac{\log(p/q)}{\log(1/q)} \right) + O(K^{-1}) \right).
\]

However, if \( k \) is close to the right boundary of (34), more precisely, \( k = \alpha_2 (1 - \varepsilon_n) L_n \), where \( \varepsilon_n = o(1) \), then

\[
\rho = -2 + \frac{\varepsilon_n}{\alpha_2 \beta_2 (-2)} + O(\varepsilon_n^2).
\]

Thus \( \rho = O(1) \).

From (41), we see that if \( \rho \geq 1 \) and \( k \) satisfies (34), then \( k\beta_2(\rho) \) and

\[
k(p/q)^\rho \geq \frac{K_n}{\log(p/q)} + o(1);
\]

on the other hand, if \( \rho \geq -2 + K_n L_n^{-1/2} \), then \( k(p + 2)^2 \geq K_n^2 \). Thus the \( O \)-term in (35) is small if we choose \( K_n \) sufficiently large.

**3.4.3. More transparent behaviors of \( \mu_{n,k} \).** Before we present a formal proof of Theorem 2, we first discuss more transparent behaviors of \( \mu_{n,k} \) in some specified ranges.

The central range: \( \alpha \in [\alpha_1 + \varepsilon, \alpha_2 - \varepsilon] \). In this case, \( G_1 \) is bounded and \( G_1(p; x) \sim G_1(\rho'; x) \), where

\[
\rho' := \frac{1}{\log(p/q)} \log \left( \frac{1 - \alpha \log(1/p)}{\alpha \log(1/q) - 1} \right); \tag{42}
\]

also \( \beta_2(\rho) \sim \beta_2(\rho') \). Note that \( g(\rho + it_j) = 1 - p^{it_j}/(p^{-\rho} + q^{-\rho}) \) and

\[
G_1 \left( \rho; \log_{p/q} p^k n \right) = G_1 \left( \rho; \log_{p/q} q^k n \right).
\]
More precisely, if \( k = \alpha(L_n + x\sqrt{\alpha\beta_2(\rho')L_n}) \), where \( \alpha \in [\alpha_1 + \varepsilon, \alpha_2 - \varepsilon] \) and \( x = o(L_n^{1/6}) \), then

\[
\mu_{n,k} = G_1(\rho'; \log_{p/q} p^n) \frac{n^{-\rho'}(p^{-\rho'} + q^{-\rho'})^k}{\sqrt{2\pi\alpha\beta_2(\rho')L_n}} e^{-x^2/2} \left( 1 + O\left( \frac{1 + |x|^3}{\sqrt{L_n}} \right) \right),
\]

uniformly in \( x \). In particular, when \( \alpha = 1/h \), where \( h := p\log(1/p) + q\log(1/q) \) is the entropy of the Bernoulli variate, then \( \rho' = -1 \), and it follows that

\[
\mu_{n,k} = \sqrt{n} G_1(-1; \log_{p/q} p^n) \frac{n}{\log(p/q) \sqrt{2\pi pq}} e^{-x^2/2} \left( 1 + O\left( \frac{1 + |x|^3}{\sqrt{L_n}} \right) \right),
\]

uniformly for \( x = o(L_n^{1/6}) \). Other approximations can be derived for \( L_n^{1/6} \ll x = o(\sqrt{L_n}) \). Thus \( \mu_{n,k} \) reaches the maximum for \( k \) near \( L_n/h + O(1) \); also, \( \mu_{n,k} \) increases with \( k \) when \( \alpha < 1/h \) and decreases with \( k \) when \( \alpha > 1/h \); see Figure 3. See also Figure 2 for a plot of \( G_1(-1; x) \) for a few \( p \)'s.

**The left boundary:** \( \rho \to -2^+ \) and \( \rho + 2 \gg L_n^{-1/2} \). In this case, the dominant periodicity vanishes because

\[
G_1(\rho; x) \sim \frac{|g(-2)|}{\rho + 2} = \frac{2pq}{(p^2 + q^2)(\rho + 2)};
\]

thus

\[
\mu_{n,k} \sim \frac{2}{\sqrt{2\pi \log(p/q)(\rho + 2)}} k^{-1/2} n^{-\rho} (p^{-\rho} + q^{-\rho})^k.
\]

**The right boundary:** \( k/L_n \to 1/\log(1/q)^+ \). In this case, \( \rho \to \infty \) and \( \rho = O(LL_n) \). The periodicity in the leading term of (35) does not vanish because we have

\[
G_1(\rho; x) \sim \sum_{j \in \mathbb{Z}} \Gamma(\rho + 1 + it_j) e^{-2j\pi ix},
\]

and \( G_1 \) is not bounded. Indeed, the periodicity becomes more pronounced for increasing \( \rho \) since

\[
\left| \Gamma(\rho + 1 + it) \right| \Gamma(\rho + 1) = O\left( e^{-t^2/(2\rho) + O(t^4/\rho^3)} \right)
\]

for large \( \rho \) and \( t = o(\rho) \); see Figure 4. This estimate also implies that

\[
G_1(\rho; x) = O\left( \sum_{j \in \mathbb{Z}} |\Gamma(\rho + 1 + it_j)| \right) = O\left( e^{-\rho \rho^{\rho+1}} = O\left( \rho^{1/2} \Gamma(\rho + 1) \right) \right).
\]

The order is tight. This means that even if we normalize \( G_1(\rho; x) \) by \( \Gamma(\rho + 1) \), \( |G_1(\rho; x)| \) still goes to infinity with \( \rho \).
3.4.4. Proof of Theorem 2. In view of (25) (more generally, de-Poissonization Proposition 1), we need only evaluate \( \hat{M}_k(n) \) and obtain precise local expansions for \( \hat{M}_k(ne^{i\theta}) \) when \( |\theta| \leq \theta_0 \) in order to estimate the first integral of (25). We first focus on estimating \( \hat{M}_k(n) \) and then extend the same approach to derive the asymptotics of \( \hat{M}_k(ne^{i\theta}) \). This suffices to prove that \( \mu_{n,k} \sim \hat{M}_k(n) \). Later in subsection 3.8 we refine this analysis to obtain a better error term.

In order to evaluate \( \hat{M}_k(n) \) by the inverse Mellin transform, first we move the line of integration of (6) to \( \Re(s) = \rho \) so that

\[
\hat{M}_k(n) = \frac{1}{2\pi} \int_{-\infty}^{\infty} J_k(n; \rho + it)dt,
\]

where \( \rho > -2 \) is the saddle-point chosen according to (36) and \( J_k(n; s) := n^{-s}\Gamma(s + 1)g(s)(p^{-s} + q^{-s})^k \). We now show that the above integral with \( |t| \geq \sqrt{L_n} \) is asymptotically smaller than the dominant term in (35) and then assess the main contribution of saddle-points falling into the range \( |t| \leq \sqrt{L_n} \).

Estimate of the integral when \( |t| \geq \sqrt{L_n} \). Assume from now on that \( \rho \) is chosen as described above in (36).

Since our \( \rho > -2 \) satisfies (40), we have, by (9),

\[
\frac{1}{2\pi} \int_{|t| \geq \sqrt{L_n}} J_k(n; \rho + it)dt = O \left( \int_{\sqrt{L_n}}^{\infty} |\Gamma(\rho + 1 + it)|dt \right)
= O \left( n^{-\rho}(p^{-\rho} + q^{-\rho})^k \int_{\sqrt{L_n}}^{\infty} t^{p+1/2}e^{-\pi t/2}dt \right)
= O \left( L_n^{p/2+1/4}e^{-\pi \sqrt{L_n}/2}n^{-\rho}(p^{-\rho} + q^{-\rho})^k \right).
\]

On the other hand, since \( \rho = O(\ln n) \) and \( \rho \geq -2 + K_nL_n^{-1/2} \), we then obtain

\[
L_n^{p/2+1/4}e^{-\pi \sqrt{L_n}/2} = O \left( e^{-\pi \sqrt{L_n}/2 + O(\ln^2 n)} \right) = O \left( \Gamma(\rho + 2)e^{-\sqrt{L_n}} \right)
\]

for large enough \( n \); the last \( O \)-term holds uniformly for \( \rho \geq -2 + K_nL_n^{-1/2} \) and \( \rho \) satisfying (41).

Contribution from each saddle-point. Let \( j_0 \) be the largest integer \( j \) for which \( 2j\pi / \log(p/q) \leq \sqrt{L_n} \). Then we can split the integral over \( |t| \leq \sqrt{L_n} \) as follows:

\[
\int_{|t| \leq \sqrt{L_n}} J_k(n; \rho + it)dt = \sum_{|j| \leq j_0} \int_{|t - tj| \leq \pi / \log(p/q)} J_k(n; \rho + it)dt
+ \int_{t_{j_0} = |t| \leq \sqrt{L_n}} J_k(n; \rho + it)dt.
\]

The last integral is bounded above by

\[
O \left( \Gamma(\rho + 2)n^{-\rho}(p^{-\rho} + q^{-\rho})^k e^{-\sqrt{L_n}} \right),
\]

by the same argument used above. It remains to evaluate the integrals

\[
T_j := \frac{1}{2\pi} \int_{|t - tj| \leq \pi / \log(p/q)} J_k(n; \rho + it)dt
\]

for \( |j| < j_0 \).
We first derive a uniform bound for $|p^{-\rho-it} + q^{-\rho-it}|$. By the elementary inequalities (29) and

$$\sqrt{1-x} \leq 1 - \frac{x}{2} \quad (x \in [0,1]),$$

we have

$$|p^{-\rho-it} + q^{-\rho-it}| = (p^{-\rho} + q^{-\rho}) \sqrt{1 - \frac{2p^{-\rho}q^{-\rho}}{(p^{-\rho} + q^{-\rho})^2} \left(1 - \cos \left(t \log \left(\frac{p}{q}\right)\right)\right)}$$

$$\leq (p^{-\rho} + q^{-\rho}) \left(1 - \frac{p^{-\rho}q^{-\rho}}{(p^{-\rho} + q^{-\rho})^2} \left(1 - \cos \left(\frac{t}{t_{j}} \log \left(\frac{p}{q}\right)\right)\right)\right)$$

$$\leq (p^{-\rho} + q^{-\rho}) \left(1 - \frac{2p^{-\rho}q^{-\rho}}{\pi^2(p^{-\rho} + q^{-\rho})^2} (t - t_{j})^2 \log \left(\frac{p}{q}\right)^2\right)$$

$$(46) \quad \leq (p^{-\rho} + q^{-\rho}) e^{-c_0(t-t_j)^2},$$

uniformly for $|t-t_j| \leq \pi/\log(p/q)$, where

$$c_0 = c_0(\rho) := \frac{2p^{-\rho}q^{-\rho} \log(p/q)^2}{\pi^2(p^{-\rho} + q^{-\rho})^2} = \frac{2}{\pi^2} \beta_2(\rho).$$

We now take

$$v_0 := \begin{cases} k^{-2/5} & \text{if } -2 < \rho \leq 1, \\ (c_0 k)^{-2/5} & \text{if } \rho \geq 1, \end{cases}$$

and split the integration range into two parts: $|t-t_j| \leq v_0$ and $v_0 < |t-t_j| \leq \pi/\log(p/q)$. (We assume that $k$ is so large that $v_0 < \pi/\log(p/q)$.)

First consider the case when $-2 < \rho \leq 1$. From the inequality (46), it follows that

$$\begin{align*}
T_j'' &:= \frac{1}{2\pi} \int_{v_0 \leq |t-t_j| \leq \pi/\log(p/q)} J_k(n; \rho + it) dt \\
&= O \left(\Gamma(\rho + 2 + it_j)|n^{-\rho} (p^{-\rho} + q^{-\rho})^{k} \int_{k^{-2/5}}^{\infty} e^{-c_0 k v^2} dv\right) \\
&= O \left(n^{-\rho} (p^{-\rho} + q^{-\rho})^{k} k^{-3/5} e^{-c_0 k^{1/5}} \times \begin{cases} |\Gamma(\rho + 1 + it_j)| & \text{if } j \neq 0 \\ 1 & \text{if } j = 0 \end{cases} \right)
\end{align*}$$

for each $|j| \leq j_0$.

When $\rho \geq 1$ and satisfies (34), we have

$$\begin{align*}
T_j'' &:= O \left(|\Gamma(\rho + 1 + it_j)|n^{-\rho} (p^{-\rho} + q^{-\rho})^{k} \int_{(c_0 k)^{-2/5}}^{\infty} e^{-c_0 k v^2} dv\right) \\
&= O \left(|\Gamma(\rho + 1 + it_j)|n^{-\rho} (p^{-\rho} + q^{-\rho})^{k} (c_0 k)^{-3/5} e^{-(c_0 k)^{1/5}}\right)
\end{align*}$$

for $|j| \leq j_0$. 
The dominant terms. It remains to evaluate the integrals $T_j$ for $t$ in the range $|t - t_j| \leq v_0$. Note that, by our choice of $t_j$,

$$p^{-\rho-it_j} + q^{-\rho-it_j} = p^{-it_j} (p^{-\rho} + q^{-\rho}) = q^{-it_j} (p^{-\rho} + q^{-\rho}),$$

so that

$$\frac{p^{-\rho-it} + q^{-\rho-it}}{p^{-\rho-it_j} + q^{-\rho-it_j}} = 1 + \sum_{\ell \geq 1} \frac{i^\ell(t-t_j)^\ell}{\ell!} \frac{p^{-\rho-it} \log(1/p)^\ell + q^{-\rho-it} \log(1/q)^\ell}{p^{-\rho-it_j} + q^{-\rho-it_j}},$$

$$= 1 + \sum_{\ell \geq 1} \frac{i^\ell(t-t_j)^\ell}{\ell!} \frac{p^{-\rho} \log(1/p)^\ell + q^{-\rho} \log(1/q)^\ell}{p^{-\rho} + q^{-\rho}},$$

where we recall that $t_j = 2\pi j / \log(p/q)$.

It follows that

$$\log \left( \frac{p^{-\rho-it} + q^{-\rho-it}}{p^{-\rho-it_j} + q^{-\rho-it_j}} \right) = \log \left( \frac{p^{-\rho-it} + q^{-\rho-it}}{p^{-\rho-it_j} + q^{-\rho-it_j}} \right) + \sum_{\ell \geq 1} \frac{\beta_\ell(p)}{\ell!} i^\ell(t-t_j)^\ell,$$

where, in particular,

$$\beta_1(p) = \frac{p^{-\rho} \log(1/p) + q^{-\rho} \log(1/q)}{p^{-\rho} + q^{-\rho}}.$$

The remaining manipulation by using the saddle-point method is then straightforward. We use the local expansions

$$\left( \frac{p^{-\rho-it} + q^{-\rho-it}}{p^{-\rho-it_j} + q^{-\rho-it_j}} \right)^k = \exp \left( k \sum_{1 \leq \ell \leq 3} \frac{\beta_\ell(p)}{\ell!} i^\ell(t-t_j)^\ell + O(k|\beta_4(p)||t-t_j|^4) \right)$$

and

$$\Gamma(\rho + 1 + it)g(\rho + it)$$

$$\begin{cases} C_0 + C_1 t(t-t_j) + O \left( \frac{(t-t_j)^2}{(\rho+2)^2} \right) & \text{if } -2 < \rho \leq 1, \\
\Gamma(\rho + 1 + it_j) e^{(\log \rho) i(t-t_j)} (1 + C_2 i(t-t_j) + O(|C_2|^3 |t-t_j|^2)) \times (g(\rho + it_j) + g'(\rho + it_j) i(t-t_j) + O(|t-t_j|^2)) & \text{if } \rho \geq 1,
\end{cases}$$

where

$$\begin{cases} C_0 := \Gamma(\rho + 1 + it_j) g(\rho + it_j), \\
C_1 := g(\rho + it_j) \Gamma(\rho + 1 + it_j) \psi(\rho + 1 + it_j) + g'(\rho + it_j) \Gamma(\rho + 1 + it_j),
\end{cases}$$

$$\psi(s) = \Gamma'(s)/\Gamma(s)$$

being the logarithmic derivative of the Gamma function, and

$$C_2 := \psi(\rho + 1 + it_j) - \log \rho \quad (\rho \geq 1).$$

Here $C_0$ and $C_1$ are defined to be their limits when $\rho = -1$ and $j = 0$, namely,

$$\begin{cases} C_0 := p \log(1/p) + q \log(1/q), \\
C_1 := -\frac{2\rho-1}{2} (p \log(p)^2 - q \log(q)^2) - C_0 \gamma - 2pq \log(p) \log(q).
\end{cases}$$
Note that \( \psi(\rho + 1 + it_j) - \log \rho = O(\log(1 + |t_j|)) \). It follows that for \( |j| < j_0 \)

\[
T_j = \frac{g(\rho + it_j)}{\sqrt{2\pi \beta_2(\rho)k}} \Gamma(\rho + 1 + it_j)n^{-\rho-it_j} (p^{-\rho} + q^{-\rho})^k \rho^{-ikt_j} \times \left(1 + O\left(\frac{1}{k\beta_2(\rho)} + \frac{1}{k(\rho+2)^2}\right)\right).
\]

Summing over all \( |j| < j_0 \) and collecting all estimates, we obtain

\[
\tilde{M}_k(n) = \frac{n^{-\rho}(p^{-\rho} + q^{-\rho})^k}{\sqrt{2\pi \beta_2(\rho)k}} \sum_{|j| < j_0} g(\rho + it_j)\Gamma(\rho + 1 + it_j)(p^k n)^{-it_j} \times \left(1 + O\left(\frac{1}{k(p/q)\rho} + \frac{1}{k(\rho+2)^2}\right)\right).
\]

An asymptotic approximation to \( \tilde{M}_k(z) \). To complete the de-Poissonization, we need a more precise expansion of \( \tilde{M}_k(ne^{i\theta}) \) for small \( \theta \). The above proof by the saddle-point method can be easily extended mutatis mutandis to \( \tilde{M}_k(z) \) for complex values of \( z \) lying in the right half-plane since we can write (7) as

\[
\tilde{M}_k(ne^{i\theta}) = \frac{1}{2\pi i} \int_{(\rho)} n^{-s} e^{-i\theta s} \Gamma(s+1) g(s) (p^{-s} + q^{-s})^k ds,
\]

where \( \rho > -2 \) and \( |\theta| \leq \pi/2 - \varepsilon \). The result is

\[
\tilde{M}_k(ne^{i\theta}) = \frac{(p^{-\sigma} + q^{-\sigma})^k}{\sqrt{2\pi \beta_2(\rho)k}} \sum_{|j| < j_0} g(\sigma + it_j)\Gamma(\sigma + 1 + it_j)(ne^{i\theta})^{-\sigma-it_j} \rho^{-ikt_j} \times \left(1 + O\left(\frac{1}{k(p/q)\rho} + \frac{1}{k(\rho+2)^2}\right)\right),
\]

uniformly for \( |\theta| \leq \pi/2 - \varepsilon \) and \( k \) lying in the range (34). Note that the index of the sum can be extended to infinity, but it is easier to manipulate a finite sum than an infinite series since we substitute the right-hand side into the Cauchy integral (13) and then integrate term by term. This completes the proof of (35).

3.5. Range (IV): A singularity analysis. We consider range (IV) first, leaving to the next subsection the analysis in the transitional range when \( k = \alpha_2 L_n + o(L_n^{2/3}) \).

We show that, for \( k \geq \alpha_2 L_n + K_n \sqrt{L_n} \), the asymptotics of the expected profile \( \tilde{M}_k(n) \) are dictated by the simple pole at \( s = -2 \) in (6) or, structurally, by the number of pairs of input-strings sharing the same prefixes of length at least \( k \).

**Theorem 3.** If

\[
k \geq \alpha_2 \left(L_n + K_n \sqrt{\alpha_2 \beta_2(-2)L_n}\right),
\]

where \( \beta_2 \) is defined in (37), then

\[
\mu_{n,k} = 2pqn^2(p^2 + q^2)^{k-1} \left(1 + O\left(K_n^{-1} e^{-K_n^2/2 + O(K_n^2/\sqrt{L_n})}\right)\right),
\]

uniformly for \( 1 \ll K_n = o(\sqrt{L_n}) \).
Proof. To prove (50), we move the line of integration (by absolute convergence of the integral) of the integral in (6) to \( \Re(s) = \varrho \), where

\[
\varrho := -2 - \frac{K_n}{\sqrt{\alpha_2 \beta_2 (-2) L_n}}.
\]

Thus \( \tilde{M}_k(ne^{i\theta}) \) equals the residue of the integrand at \( s = -2 \) (the dominant term in (50)) plus the integral along \( \Re(s) = \varrho \):

\[
\tilde{M}_k(ne^{i\theta}) = |g(-2)|n^2 e^{-2i\theta} (p^2 + q^2)^k + \frac{1}{2\pi} \int_{-\infty}^{\infty} J_k(ne^{i\theta}; \varrho + it) \, dt,
\]

where \( |g(-2)| = 2pq/(p^2 + q^2) \). It remains only to estimate the last integral. By the same analysis used for \( T_j'' \) (see (47)) and the inequality (46), we have

\[
\frac{1}{2\pi} \left( \int_{|t| \leq \pi/\log(p/q)} + \sum_{|j| \geq 1} \int_{|t-t_j| \leq \pi/\log(p/q)} \right) J_k(ne^{i\theta}; \varrho + it) \, dt
\]

\[
= O \left( |\Gamma(\varrho + 1)|n^{-\varrho} (p^{-\varrho} + q^{-\varrho})^k \int_{|t| \leq \pi/\log(p/q)} e^{-c\varrho \varrho^2} dt \right)
\]

\[
+ O \left( n^{-\varrho} (p^{-\varrho} + q^{-\varrho})^k \sum_{|j| \geq 1} \left| \Gamma \left( \varrho + 1 + \frac{2|j| - 1}{\log(p/q)} \pi i \right) \right| e^{(2|j| + 1)\pi|\theta|/\log(p/q)} \right)
\]

\[
\times \int_{|t-t_j| \leq \pi/\log(p/q)} e^{-c\varrho \varrho^2 (t-t_j)^2} dt
\]

\[
= O \left( \frac{k^{-1/2}}{|\varrho + 2|} n^{-\varrho} (p^{-\varrho} + q^{-\varrho})^k \right)
\]

\[
= O \left( K_n^{-1} n^{-\varrho} (p^{-\varrho} + q^{-\varrho})^k \right),
\]

where we used (9) to bound the sum

\[
\sum_{|j| \geq 1} \left| \Gamma \left( \varrho + 1 + \frac{2|j| - 1}{\log(p/q)} \pi i \right) \right| e^{(2|j| + 1)\pi|\theta|/\log(p/q)}
\]

\[
= O \left( \sum_{|j| \geq 1} (2|j| - 1)^{e^{1/2}} \exp \left( - \frac{\pi^2 (2|j| - 1)}{2 \log(p/q)} + \frac{(2|j| + 1)\pi|\theta|}{\log(p/q)} \right) \right)
\]

\[
= O(1),
\]

uniformly for \( |\theta| \leq \pi/2 - \varepsilon \).

By our choice of \( \varrho \) and by straightforward expansion, we have

\[
\frac{K_n^{-1} n^{-\varrho} (p^{-\varrho} + q^{-\varrho})^k}{n^2 (p^2 + q^2)^k} = O \left( K_n^{-1} e^{-L_n(e+2) + \frac{\alpha_2}{2} (e+2) + \frac{\beta_2}{2} (e+2)^2 + O(k|\theta|^2)} \right)
\]

\[
= O \left( K_n^{-1} e^{-K_n^2/2 + O(K_n^3/\sqrt{L_n})} \right).
\]

Thus

\[
\tilde{M}_k(ne^{i\theta}) = |g(-2)|(ne^{i\theta})^2(p^2 + q^2)^k \left( 1 + O \left( K_n^{-1} e^{-K_n^2/2 + O(K_n^3/\sqrt{L_n})} \right) \right),
\]

(51)
uniformly for $|\theta| \leq \pi/2 - \varepsilon$. Substituting this into (25), we deduce the desired result (50).

Remarks. (i) When $K_n \geq \varepsilon \sqrt{L_n}$, we can either take $K_n = \varepsilon \sqrt{L_n}$ or refine the analysis to give a better error term.

(ii) The asymptotic approximation (50) can also be derived from the exact expression (10) by using only elementary arguments.

(iii) Also note that the range (49) implies that the saddle-point $\rho$ satisfies $\rho \leq -2 - K_n/\sqrt{L_n}$, but the contribution from this saddle-point is asymptotically negligible (compared to the polar singularity).

3.6. Range (III): A uniform analysis. We consider in this subsection the transitional range $k = \alpha_2 L_n + o(L_n^{2/5})$ and show that the transitional behavior of $\mu_{n,k}$ in this range is well described by a Gaussian distribution function.

**Theorem 4.** If

\begin{equation}
(52) \quad k = \alpha_2 \left( L_n + \xi \sqrt{\alpha_2 \beta_2(-2) L_n} \right),
\end{equation}

where $\xi = \xi_{n,k} = o(L_n^{1/6})$, then

\begin{equation}
(53) \quad \mu_{n,k} = |g(-2)| \Phi(\xi) n^2 (p^2 + q^2)^k \left( 1 + O \left( \frac{1 + |\xi|^3}{\sqrt{L_n}} \right) \right),
\end{equation}

uniformly in $\xi$, where $\Phi(\xi) = (2\pi)^{-1/2} \int_{-\infty}^{\xi} e^{-t^2/2} dt$.

**Proof.** We assume first that $k$ satisfies (52) and $k < \alpha_2 L$ (or $\xi < 0$). We move the line of integration of the integral in (11) to $\mathbb{R}(s) = \rho$, where $\rho$ is taken to be of the same form as in (40); asymptotically

\begin{equation}
(54) \quad \rho = -2 - \frac{\xi}{\sqrt{\alpha_2 \beta_2(-2) L_n}} + O \left( \xi^2 L_n^{-1} \right).
\end{equation}

By a similar analysis as the proof of Theorem 3, we obtain

\[
\tilde{M}_k(ne^{i\theta}) = \frac{1}{2\pi} \int_{|t| \leq L_n^{-2/5}} J_k(ne^{i\theta}; \rho + it) dt + O \left( \Gamma(\rho + 1 + iL_n^{-2/5}) |n^{-\rho} (p^{-\rho} + q^{-\rho})^k e^{-c_0 L_n^{1/5}} \right) + O \left( k^{-1/2} n^{-\rho} (p^{-\rho} + q^{-\rho})^k \right),
\]

where $|\theta| < \pi/2$. By (54), we have

\[
|\Gamma(\rho + 1 + iL_n^{-2/5})| = O \left( \frac{1}{|\xi| L_n^{-1/2} + L_n^{-2/5}} \right) = O(L_n^{2/5}).
\]

It follows that

\[
\tilde{M}_k(ne^{i\theta}) = \frac{1}{2\pi} \int_{|t| \leq L_n^{-2/5}} J_k(ne^{i\theta}; \rho + it) dt + O \left( k^{-1/2} n^{-\rho} (p^{-\rho} + q^{-\rho})^k \right).
\]

Note that since $s \mapsto \Gamma(s + 1) + 1/(s + 2)$ is analytic for $|s + 2| \leq 1 - \varepsilon$, we have

\[
\tilde{M}_k(ne^{i\theta}) = \frac{|g(-2)|}{2\pi} \int_{|t| \leq L_n^{-2/5}} \frac{n^{-\rho-it} e^{-i\theta(\rho+it)}}{\rho + 2 + it} (p^{-\rho-it} + q^{-\rho-it})^k dt + O \left( k^{-1/2} n^{-\rho} (p^{-\rho} + q^{-\rho})^k \right).
\]
The integral on the right-hand side is evaluated as follows:

\[
\frac{|g(-2)|}{2\pi} \int_{|t| \leq L_n^{-2/5}} \frac{n^{-\rho-it}e^{-i\theta(\rho+it)}}{\rho+2+it} (p^{-\rho-it} + q^{-\rho-it})^k \, dt
\]

\[
= \frac{|g(-2)|}{2\pi} n^{-\rho} e^{-i\theta\rho} (p^{-\rho} + q^{-\rho})^k \int_{|t| \leq L_n^{-2/5}} \frac{e^{it-\beta_2(\rho)kt^2/2 + O(k|t|)}}{\rho+2+it} \, dt
\]

(55)

\[
= \frac{|g(-2)|}{2\pi} n^{-\rho} e^{-i\theta\rho} (p^{-\rho} + q^{-\rho})^k \int_{-\infty}^{\infty} e^{-t^2/2} \left(1 + O\left(\frac{|t| + |t|^3}{\sqrt{L_n}}\right)\right) dt,
\]

where

\[
\xi_0 := (\rho + 2)\sqrt{\beta_2(\rho)k} > 0.
\]

Note that \(\xi_0 = -\xi + O\left(\xi^2 L_n^{-1/2}\right)\) by (52) and (54). Since \(\xi_0 > 0\), we have

\[
\frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-t^2/2} \left(1 + O\left(\frac{|t| + |t|^3}{\sqrt{L_n}}\right)\right) dt = O\left(L_n^{-1/2} \int_0^\infty (v + v^3)e^{-v^2/2-v\xi_0} dv\right).
\]

Observe that

(56)

\[
e^{x^2/2}\Phi(-x) = \begin{cases} 
  O\left(x^{-1}\right) & \text{if } x \to \infty, \\
  O\left(e^{x^2/2}\right) & \text{if } x \to -\infty.
\end{cases}
\]

Also

\[
\int_0^\infty (v + v^3)e^{-v^2/2-vx} dv = \begin{cases} 
  O\left(x^{-2}\right) & \text{if } x \to \infty, \\
  O\left(|x|^3e^{x^2/2}\right) & \text{if } x \to -\infty,
\end{cases}
\]

so that

\[
\int_0^\infty v^3 e^{-v^2/2-vx} dv = O\left(e^{x^2/2}\Phi(-x)(1 + |x|^3)\right).
\]

Thus

\[
\tilde{M}_k(ne^{i\theta}) = |g(-2)|\left|ne^{i\theta}\right|^{-\rho} (p^{-\rho} + q^{-\rho})^k e^{\xi_0^2/2}\Phi(-\xi_0) \left(1 + O\left(\frac{1 + |\xi|^3}{\sqrt{L_n}}\right)\right)
\]

(57) 

\[+ O\left(k^{-1/2}n^{-\rho} (p^{-\rho} + q^{-\rho})^k\right),\]
uniformly for $|\theta| \leq \pi/2 - \varepsilon$. Substituting this in (25) and using the expansions

$$n^{\rho} (p^{-\rho} + q^{-\rho})^k = n^2 (p^2 + q^2)^k e^{-\xi^2/2 + O(1/\xi^3 L^{-1/2})},$$

$$e^{\xi^2/2} \Phi(\xi_0) = e^{\xi^2/2} \Phi(\xi) \left(1 + O\left(|\xi| L^{-1/2}ight)\right),$$

we deduce (53) when $\xi < 0$.

The restriction that $\xi < 0$ can now be removed by continuity (when $\xi_0 = 0$ the integral path has to be properly indented) or by a similar analysis. This proves (53).

One can easily check, by (56), that the asymptotic estimate (53) coincides with the two estimates (44) and (50) when $\xi \to -\infty$ and $\xi \to \infty$, respectively.

**Remark.** The appearance of the normal distribution function is typical when a saddle-point coalesces with a simple pole; see [83]. Also, the polynomial order (4) of $\mu_{n,k}$ now follows from (35), (50), and (53).

### 3.7. The range where the expected profile grows unbounded.

An important consequence of the preceding results is the following characterization of the range where $\mu_{n,k} \to \infty$, which also will be seen to be the range where $B_{n,k}$ is asymptotically normally distributed.

**Theorem 5.** Define

$$m_0 := \left\lceil \frac{1}{p/q - 1} \right\rceil \quad \text{and} \quad \alpha_3 := \frac{2}{\log(p^2 + q^2)}.
$$

Then $\mu_{n,k} \to \infty$ iff

$$\alpha_1 \left(L_n - LLL_n - \log m_0 + m_0 \log \left(\frac{p}{q}\right) - \frac{LLL_n - K_n}{m_0 LLL_n}\right) \leq k \leq \alpha_3 \left(L_n - K_n\right)$$

as $n \to \infty$.

**Proof.** Consider first the upper bound. If $k \leq \alpha_3 L_n - x$, then

$$n^2(p^2 + q^2)^k \geq (p^2 + q^2)^{-x},$$

which tends to infinity if $x \to \infty$; on the other hand, if $k \geq \alpha_3 L_n - x$, then the reverse inequality holds and the right-hand side remains bounded if $x$ is less than a positive constant.

For the lower bound, we use the estimate (24). First, if $k \leq k_0 = \alpha - 1 \left(L_n - LLL_n + \log(p/q - 1)\right)$ (see (20)), then

$$\mu_{n,k} = \Theta(q^k ne^{-q^k n}) = o(1).$$

Next, if $k_{m-1} \leq k \leq k_m$, $m \geq 1$, then by (24)

$$\mu_{n,k} = \Theta(S_{n,k,m}) = \Theta(L_n^{m-e^\eta/(p/q - 1)} LL_n),$$

where $k$ is written in the form (31). Since $\eta \in [0, \log(p/q)]$, we have

$$m - \frac{p}{p - q} \leq m - \frac{e^\eta}{p/q - 1} \leq m - \frac{q}{p - q}.$$

Also, by the definition of $m_0$, we have the inequalities

$$m_0 - 1 < \frac{q}{p - q} = \frac{1}{p/q - 1} \leq m_0.$$
Thus if \( m \leq m_0 - 1 \), then
\[
m - \frac{e^\eta}{p/q - 1} \leq m - \frac{q}{p - q} < m - m_0 + 1 \leq 0,
\]
implying that \( \mu_{n,k} \to 0 \) for \( k \leq k_{m_0 - 1} \). Similarly, since
\[
m_0 \leq \frac{p}{p - q} < m_0 + 1,
\]
we have
\[
m - \frac{e^\eta}{p/q - 1} \geq m - \frac{p}{p - q} > m - m_0 - 1 \geq 0,
\]
when \( m \geq m_0 + 1 \). Therefore, \( \mu_{n,k} \to \infty \) if \( k \geq k_{m_0} \) (and remains in the range \( k \leq \alpha_1(L_n - LLL_n + K_n) \)).

The remaining range is \( k_{m_0 - 1} \leq k \leq k_{m_0} \) in which \( \mu_{n,k} = \Theta(L_n^{m_0-e^\eta/(p/q-1)} LLL_n) \), where
\[
k = \alpha_1(L_n - LLL_n + \log(p/q - 1) + m_0 \log(p/q) - \eta).
\]
We distinguish three cases: (i) if
\[
\eta \geq \log m_0 + \log(p/q - 1) + \frac{LLL_n + K_n}{m_0 LLL_n},
\]
then \( \mu_{n,k} = \Theta(L_n^{m-e^\eta/(p/q-1)} LLL_n) \) and
\[
L_n^{m-e^\eta/(p/q-1)} LLL_n \leq e^{-K_n} \to 0;
\]
(ii) if
\[
\eta = \log m_0 + \log(p/q - 1) + \frac{LLL_n + x}{m_0 LLL_n},
\]
then
\[
\mu_{n,k} \sim S_{n,k,m_0} \sim \frac{m_0^{m_0}}{(m_0 - 1)!} e^{-x},
\]
uniformly for \( x = O(1) \); and
(iii) if
\[
\eta \leq \log m_0 + \log(p/q - 1) + \frac{LLL_n - K_n}{m_0 LLL_n},
\]
then \( \mu_{n,k} = \Theta(L_n^{m-e^\eta/(p/q-1)} LLL_n) \) and
\[
L_n^{m-e^\eta/(p/q-1)} LLL_n \geq e^{K_n} \to \infty.
\]
Thus \( \mu_{n,k} \) is bounded away from zero and infinity in the second case.

This proves the theorem when \( k \) lies in ranges (I) and (IV). The remaining cases follow easily from (35) and (53).
Corollary 3. Let

\[
\hat{k} := \alpha_1 \left( L_n - \text{LLL}_n - \log m_0 + m_0 \log(p/q) - \frac{\text{LLL}_n}{m_0 \text{LL}_n} \right),
\]

where \( m_0 = \lceil 1/(p/q - 1) \rceil \). Then (i) \( \mu_{n,k} \to \infty \) for \( \lceil \hat{k} \rceil \leq k \leq \alpha_3 (L_n - K_n) \); (ii) \( \mu_{n,k} \to 0 \) for \( k \leq \lceil \hat{k} \rceil - 2 \); and (iii)

\[
\mu_{n,\lceil \hat{k} \rceil - 1} \left\{ \begin{array}{ll} = \Theta(1) & \text{if } \{ \hat{k} \} = O(\text{LLL}_n^{-1}), \\ \\ \to 0 & \text{otherwise}. \end{array} \right.
\]

Proof. The proof is similar to that of Theorem 5. We consider only the last case. First write

\[
\lceil \hat{k} \rceil - 1 = \hat{k} - \{ \hat{k} \} = \alpha_1 \left( L_n - \text{LLL}_n + \log(p/q - 1) + m_0 \log(p/q) - \eta' \right),
\]

where

\[
\eta' = \log m_0 + \log \left( \frac{p}{q} - 1 \right) + \{ \hat{k} \}/\alpha_1 + \frac{\text{LLL}_n}{m_0 \text{LL}_n}.
\]

(We assume that \( \hat{k} \) is not an integer.) Then we follow the same proof as above by distinguishing three cases. In particular, the case when \( \hat{k} \) is an integer is also covered by the bounded case.

The result is to be compared with Pittel’s result in [65], which says that the probability that the shortest path equals either \( \langle \kappa_n \rangle \) or \( \langle \kappa_n \rangle + 1 \) tends to 1, where \( \langle x \rangle \) denotes the nearest integer to \( x \) and

\[
\kappa_n = \alpha_1 \left( L_n - \text{LLL}_n - \log \max_{j \geq 1} j(q/p)^j \right).
\]

Note that

\[
- \log \max_{j \geq 1} j(q/p)^j = - \log m_0 + m_0 \log(p/q).
\]

Our result is slightly more precise; see section 8.

3.8. Refinement of \( \mu_{n,k} \) by de-Poissonization. All expansions for \( \mu_{n,k} \) that we have derived so far are in terms of slowly decreasing powers of \( L_n^{-1} \) or \( \text{LL}_n^{-1} \), which will turn out to be insufficient for the asymptotics of the variance because of cancellation of dominant terms. Thus in this section we derive a more effective expansion for \( \mu_{n,k} \) in terms of \( \hat{M}_k(n) \) and its higher derivatives; namely, we derive an expression of the form (19). The major difference here is that we do not substitute the asymptotic expansions for \( \hat{M}_k(n) \) into the Cauchy integral representation for \( \mu_{n,k} \), resulting in a less explicit asymptotic approximation to \( \mu_{n,k} \) but with a much better error term.

We start with a lemma in which we again use \( k_0 = \alpha_1 (L_n - \text{LLL}_n + \log(p/q - 1)) \).

Lemma 4. Define

\[
\rho_0 := \begin{cases} q^k & \text{if } 1 \leq k \leq k_0, \\ \rho & \text{if } \rho \geq 1 \text{ and } k \geq k_0, \\ 1 & \text{if } \rho \leq 1, \end{cases}
\]

(59)
where $\rho$ is given by (36). Then

$$
\hat{M}_k^{(\ell)}(ne^{i\theta}) = O \left( \rho_0 \rho^{n-\ell} \hat{M}_k(n) \right),
$$

uniformly for $\theta = o(\mathcal{L}n^{-1/2})$.

Proof. If $\ell \geq 1$, then, by (8),

$$
\hat{M}_k^{(\ell)}(z) = \sum_{0 \leq j < k} \binom{k-1}{j} (p^i q^{k-1-j})^\ell \hat{M}_1^{(\ell)}(z)
$$

$$
= \sum_{0 \leq j < k} \binom{k-1}{j} (p^i q^{k-j})^\ell + 1 \rho^n \rho^q^{j+1} \rho^2 \left( 1 + O \left( |z|^{-1} \right) \right)
$$

as $|z| \to \infty$ and $\Re(z) > 0$. If $1 \leq k \leq k_0$ (see (20)), then a proof similar to (and simpler than) that of (30) shows that

$$
\hat{M}_k^{(\ell)}(ne^{i\theta}) = O \left( q^{k+1} ne^{-q} n^\theta \right) = O \left( \rho_0 \rho^{n-\ell} \hat{M}_k(n) \right),
$$

uniformly for $\theta = o(\mathcal{L}n^{-1/2})$. If $k_{m-1} \leq k \leq k_m$, where $m \geq 1$, then the proof of (30) is also easily amended and we obtain

$$
\hat{M}_k^{(\ell)}(ne^{i\theta}) = O \left( k^m (p^m q^{k-m})^\ell + 1 ne^{-p^m q^{k-m} n^\theta} \right) = O \left( \mathcal{L}n^{\ell} n^{-\ell} \hat{M}_k(n) \right),
$$

uniformly for $\theta = o(\mathcal{L}n^{-1/2})$. Note that $\rho = O(\mathcal{L}n)$ when $k_{m-1} \leq k \leq k_m$, $m \geq 1$.

For the proof of (60) in the remaining ranges of $k$, we use the integral representation

$$
\hat{M}_k^{(\ell)}(z) = \frac{(-1)^\ell}{2\pi i} \int_{(\rho)} s(s+1)\cdots(s+\ell) \zeta^{-s-\ell} \Gamma(s+1) g(s) (p^{-s} + q^{-s})^k \, ds
$$

and a simpler analysis than that given above for $\hat{M}_k(z)$. In particular, when $k$ lies in the saddle-point range (II) and $\rho \geq 1$, we have, by the same analysis used for (46),

$$
\hat{M}_k^{(\ell)}(ne^{i\theta})
$$

$$
= O \left( n^{-\rho-\ell} \sum_{j \in \mathbb{Z}} |\rho + it_j|^\ell |\Gamma(\rho + 1 + it_j)| \int_{|t-t_j| \leq \pi / \log(p/q)} |(p^{-\rho-it} + q^{-\rho-it})^k| \, dt \right)
$$

$$
= O \left( k^{-1/2} (q/p)^{\rho/2} (p^{-\rho} + q^{-\rho})^{k-n-\rho-\rho'^k} \sum_{j \in \mathbb{Z}} |1 + it_j|^\ell |\Gamma(\rho + 1 + it_j)| \right)
$$

$$
= O \left( k^{-1/2} (q/p)^{\rho/2} (p^{-\rho} + q^{-\rho})^{k-n-\rho-\rho'} \right)
$$

$$
= O \left( \rho^{n-\ell} \hat{M}_k(n) \right),
$$

uniformly for $|\theta| \leq \pi/2 - \varepsilon$. The other cases are treated similarly. Alternately, we can use the estimates (48), (51), and (57) for $\hat{M}_k(ne^{i\theta})$ and the integral formula

$$
\hat{M}_k^{(\ell)}(z) = \frac{\ell!}{2\pi i} \int_{|w-z| \leq \varepsilon |z| / \rho_0} \frac{\hat{M}_k(w)}{(w-z)^{\ell+1}} \, dw,
$$
following a standard analysis (referred to as Ritt’s theorem in [61, pp. 9–10]).

An application of Proposition 1 (analytic de-Poissonization) and the above lemma leads to our refinement.

**Theorem 6.** If \( q^{2k} n \to 0 \), then

\[
\mu_{n,k} = \bar{M}_k(n) - \frac{n}{2} \bar{M}_k''(n) + O \left( \rho_0^2 n^{-1/2} \bar{M}_k(n) \right),
\]

where \( \rho_0 \) is given in (59).

**Proof.** By (26) and (60), we can take \( \delta(n) = \rho_0 / n \), which is \( o(n^{-1/2}) \) if \( q^{2k} n \to 0 \).

Remark. The condition that \( q^{2k} n \to 0 \) is also necessary for \( \mu_{n,k} \sim \bar{M}_k(n) \) because otherwise \( \mu_{n,k} \sim q^k n(1 - q^k)^{n-1} \), which is not asymptotically equivalent to \( \bar{M}_k(n) \). Note also that (61) and (60) imply that \( \mu_{n,k} = \bar{M}_k(n) (1 + O(\rho_0^2 n^{-1})) \).

4. Variance of the external profile. Asymptotic approximations to \( \sigma^2_{n,k} := \text{Var}(B_{n,k}) \) are derived in this section. It turns out that the variance is of the same order as the mean in all ranges, implying that the standard deviation is small; therefore we expect asymptotic normality when the variance tends to infinity with \( n \). The calculations here are more involved due to the cancellation of dominant orders of \( \mu_{n,k}^2 \). The key idea is a suitable manipulation of the corresponding de-Poissonized approximations for the mean and the second moments.

4.1. Recurrence and generating functions of the second moment. Let \( \nu_{n,k} := \text{E}(B_{n,k}^2) \) denote the second moment of \( B_{n,k} \). By (1), we have the recurrence

\[
\nu_{n,k} = \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j} (\nu_{j,k-1} + \nu_{n-j,k-1}) + \omega_{n,k}
\]

for \( n, k \geq 1 \) with \( \nu_{n,0} = \delta_{n,1} \), where

\[
\omega_{n,k} := 2 \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j} \mu_{j,k-1} \mu_{n-j,k-1}.
\]

**Generating functions.** Let \( N_k(z) := \sum_n \nu_{n,k} z^n / n! \). Then \( N_k(z) \) satisfies

\[
N_k(z) = e^{qz} N_{k-1}(pz) + e^{pz} N_{k-1}(qz) + \omega_k(z) \quad (k \geq 2)
\]

with \( N_1(z) = 2pqz^2 + M_1(z) \), where \( \omega_k(z) := 2M_{k-1}(pz)M_{k-1}(qz) \). It follows that the Poisson generating function \( \tilde{N}_k(z) := e^{-z} N_k(z) \) satisfies

\[
\tilde{N}_k(z) = \tilde{N}_{k-1}(pz) + \tilde{N}_{k-1}(qz) + \tilde{\omega}_k(z),
\]

where \( \tilde{\omega}_k(z) := 2 \tilde{M}_{k-1}(pz) \tilde{M}_{k-1}(qz) \). By iterating this functional equation, we obtain

\[
\tilde{N}_k(z) = \sum_{0 \leq \ell < k} \binom{k-1}{\ell} \tilde{N}_1(p^\ell q^{k-1-\ell} z) + \sum_{0 \leq m \leq k-2} \sum_{0 \leq \ell \leq m} \binom{m}{\ell} \tilde{\omega}_{k-m}(p^\ell q^{m-\ell} z)
\]

for \( k \geq 2 \).
Regularity of \( N_k(z) \). The following estimate is useful in justifying the application of the saddle-point method and the de-Poissonization procedure.

**Lemma 5.** Let \( z = re^{i\theta} \), where \( r \geq 0 \) and \( |\theta| \leq \pi \). Then the estimate

\[
|N_k(z)| \leq N_k(r)e^{-cr\theta^2}
\]

holds for \( r \geq 0 \) and \( |\theta| \leq \pi \) for some constant \( c \) independent of \( r, k \), and \( \theta \).

**Proof.** We start from

\[
N_k(z) = e^z \sum_{0 \leq \ell < k} \binom{k-1}{\ell} \hat{N}_1(p^\ell q^{k-1-\ell}z) + \omega_k(z) + e^z \sum_{1 \leq m \leq k-2} \sum_{0 \leq \ell \leq m} \binom{m}{\ell} \hat{\omega}_{k-m}(p^\ell q^{m-\ell}z)
\]

and apply Lemma 2 to the first sum. For the second term, we observe first that, by (26),

\[
|\omega_k(z)| \leq 2M_{k-1}(pr)M_{k-1}(qr)e^{-cr\theta^2} = \omega_k(r)e^{-cr\theta^2},
\]

uniformly for \( r \geq 0 \) and \( |\theta| \leq \pi \). It remains to estimate the last sum

\[
\left| e^z \sum_{1 \leq m \leq k-2} \sum_{0 \leq \ell \leq m} \binom{m}{\ell} \hat{\omega}_{k-m}(p^\ell q^{m-\ell}z) \right|
\]

for which we apply the same argument as that used in the proof of Lemma 2, yielding an estimate of the type (28). Collecting the three parts gives (62).

An auxiliary function for asymptotic variance. As a good approximation to \( \tilde{V}(B_{n,k}) \), define \( \tilde{V}_k(z) := \tilde{N}_k(z) - \tilde{M}_k^2(z) \). Then \( \tilde{V}_k(z) \) satisfies

\[
\tilde{V}_k(z) = \tilde{V}_{k-1}(pz) + \tilde{V}_{k-1}(qz) \quad (k \geq 2),
\]

which, by iteration, yields

\[
\tilde{V}_k(z) = \sum_{0 \leq j < k} \binom{k-1}{j} \tilde{V}_1(p^j q^{k-1-j}z),
\]

where

\[
\tilde{V}_1(z) = \tilde{M}_1(z) + 2pqz^2 e^{-z} - \tilde{M}_1^2(z).
\]

It follows that

\[
\tilde{V}_k(z) = \frac{1}{2\pi i} \int_{(\rho)} z^{-s} \Gamma(s+1) h(s) \left( p^{-s} + q^{-s} \right)^k ds,
\]

where \( \rho > -2 \) and

\[
h(s) := 1 - \frac{1}{p^{-s} + q^{-s}} - \frac{s + 1}{p^{-s} + q^{-s}} \left( \frac{p^{-s} + q^{-s} + 1}{2s+2} \right) - \frac{2p}{(1+p)^{s+2}} - \frac{2q}{(1+q)^{s+2}};
\]

compare (6).
4.2. Asymptotics of $\sigma^2_{n,k}$. In this section we show that the variance $\sigma^2_{n,k} := \mathbb{V}(B_{n,k})$ is asymptotically equivalent to $\mu_{n,k}$ when $k$ lies in range (I) and $2\mu_{n,k}$ when $k$ lies in ranges (III) and (IV), and is of the same order as $\mu_{n,k}$ in the central range (II).

**Theorem 7.** (i) If $1 \leq k \leq \alpha_1(1+o(1))L_n$, then

$$\sigma^2_{n,k} \sim \mu_{n,k}. \tag{65}$$

(ii) If $\alpha_1(L_n - LLL_n + K_n) \leq k \leq \alpha_2(L_n - K_n\sqrt{L_n})$, then

$$\sigma^2_{n,k} = G_2\left(\rho; \log\frac{p}{q}\nu k n\right) \frac{n^{-\rho}(p^{-\rho} + q^{-\rho})^k}{\sqrt{2\pi\beta_2(\rho)^k}} \left(1 + O\left(\frac{1}{k(p/q)^\rho} + \frac{1}{k(\rho + 2)^2}\right)\right), \tag{66}$$

where $\rho = \rho(n, k) > -2$ is given in (36) and

$$G_2(p; x) = \sum_{j \in \mathbb{Z}} h(\rho + it_j)\Gamma(\rho + 1 + it_j)e^{-2j\pi x} \quad (t_j := 2j\pi/\log(p/q)).$$

(iii) If $k \geq \alpha_2(1-o(1))L_n$, then

$$\sigma^2_{n,k} \sim 2\mu_{n,k}. \tag{67}$$

**Proof.** Since most details are similar to those for $\mu_{n,k}$, only the key differences will be highlighted. We separate the analysis into two overlapping cases: $1 \leq k \leq k_0 = \alpha_1(L_n - LLL_n + \log(p/q - 1))$ and $q^{2k}n \to 0.$

Consider the first case when $1 \leq k \leq k_0$. In this range, $\tilde{M}_k(ne^{i\theta}) \to 0$ for $\theta = o(LL_n^{-1/2})$ by (30) and (33). By (63) and the same proof of (30), we have

$$\tilde{V}_k(ne^{i\theta}) = \tilde{M}_k(ne^{i\theta}) \left(1 + O\left(q^kn^\rho - q^k\cos\theta\right)\right),$$

uniformly for $\theta = o(LL_n^{-1/2})$. Then since $\mu_{n,k} \to 0$, it is straightforward to show, by (30), (62), and the proof of (22), that $\sigma^2_{n,k} \sim \mu_{n,k}$ in this case, which establishes (65).

We now consider the range $q^{2k}n \to 0$ that will cover the other two cases. We will show that $\mathbb{V}(B_{n,k}) \sim \tilde{V}_k(n)$, which in turn will imply (66) and (67) (indeed, $|h(-2)| = 2|g(-2)| = 4pq/(p^2 + q^2)$).

In this case, by the integral representation (64) and the same method of proof for $\tilde{M}_k(z)$, we have

$$\tilde{V}_k^{(\ell)}(ne^{i\theta}) = O\left(\rho_0^\ell n^{-\ell} \tilde{V}_k(n)\right), \tag{68}$$

uniformly for $\theta = o(LL_n^{-1/2})$ whenever $q^{2k}n \to 0$. On the other hand, since $\tilde{M}_k(z)$ satisfies the estimate (60), we have

$$\frac{d^\ell}{dz^\ell} \tilde{M}_k^2(z) \bigg|_{z = ne^{i\theta}} = O\left(\rho_0^\ell n^{-\ell} \tilde{M}_k^2(n)\right) \quad (\ell = 0, 1, \ldots),$$
uniformly for \( \theta = o(LL^{-1/2}) \). Thus \( \tilde{N}_k(z) = \tilde{V}_k(z) + \tilde{M}_k^2(z) \) also satisfies condition (15) of Proposition 1. Therefore, by (19) of Proposition 1 we have
\[
\nu_{n,k} = \tilde{N}_k(n) - \frac{n}{2} \tilde{N}_k''(n) + O\left(\rho_0 n^{-2} \tilde{N}_k(n)\right)
\]
for \( k \geq k_0 \). Note that \( \tilde{N}_k(n) = \Theta(\mu_{n,k}^2) \) when \( \mu_{n,k} \to \infty \), but \( \tilde{N}_k(n) = \Theta(\mu_{n,k}) \) when \( \mu_{n,k} \to 0 \).

On the other hand, by (61),
\[
\mu_{n,k}^2 = \tilde{M}_k^2(n) - n \tilde{M}_k(n) \tilde{M}_k''(n) + O\left(\rho_0 n^{-2} \tilde{M}_k^2(n)\right).
\]
Therefore
\[
\sigma_{n,k}^2 = \tilde{V}_k(n) \left(1 + O(\rho_0^{-1} n^{-1} \mu_{n,k})\right),
\]
whenever \( q^{2k} n \to 0 \). Note that the \( O \)-term is at most of order \( LL_n^2 L_n^{-1/2} \). In fact, a further refinement (see (16 or [37]) shows that
\[
\sigma_{n,k}^2 = \tilde{V}_k(n) - n \tilde{M}_k''(n)^2 - \frac{n}{2} \tilde{V}_k''(n) + O\left(\rho_0^{-1} n^{-2} \tilde{N}_k(n)\right).
\]

It remains to derive asymptotic approximations to \( \tilde{V}_k(n) \), which follow the same methods of proof used for \( M_k(n) \), the only difference being changing all occurrences of \( g(s) \) to \( h(s) \). In particular, \( G_2(\rho;x) \sim G_1(\rho;x) \) when \( \rho \to \infty \), which corresponds to \( k \leq \alpha_1 (1 + o(1)) L_n \); also \( |h(-2)| = 2|g(-2)| = 4pq/(p^2 + q^2) \). This proves (66) and (67).

We conclude this section with two corollaries.

**Corollary 4.** As \( n \to \infty \), the variance \( \sigma_{n,k}^2 \to \infty \) iff the mean \( \mu_{n,k} \to \infty \).

**Corollary 5.** If \( \mu_{n,k} \to \infty \), then \( B_{n,k}/\mu_{n,k} \to 1 \) in probability.

**Proof.** The proof follows from Theorem 7 and Chebyshev’s inequality.

**5. Limiting distribution.** We prove in this section that the limiting distribution of \( B_{n,k} \) is normal if \( \sigma_{n,k} \to \infty \) and is Poisson if the variance remains bounded. Since the mean and the variance are asymptotically of the same order, the conditions can also be stated by replacing \( \sigma_{n,k} \to \infty \) by \( \mu_{n,k} \to \infty \). These results cover the range when \( k \geq \alpha_1 (L_n - LL_n + O(1)) \) and \( k \leq \alpha_2 (L_n + O(1)) \). Outside this range, \( \mu_{n,k} \to 0 \), so \( B_{n,k} \to 0 \) in probability.

**Theorem 8.** (i) If \( \sigma_{n,k} \to \infty \), then
\[
\frac{B_{n,k} - \mu_{n,k}}{\sigma_{n,k}} \xrightarrow{d} \mathcal{N}(0,1),
\]
where \( \mathcal{N}(0,1) \) denotes a standard normal random variable and \( \xrightarrow{d} \) stands for convergence in distribution.

(ii) If \( \sigma_{n,k} = \Theta(1) \), then
\[
\begin{align*}
\mathbb{P}(B_{n,k} = 2m) &= \frac{\lambda_0}{m!} e^{-\lambda_0} + o(1), \\
\mathbb{P}(B_{n,k} = 2m + 1) &= o(1),
\end{align*}
\]
uniformly for (finite) \( m \geq 0 \), where \( \lambda_0 := pqn^2(p^2 + q^2)^{k-1} \).
Note that (70) implies that $B_{n,k}$ takes asymptotically only even numbers when the mean is bounded. This indeed holds in the wider range when

$$k \geq \frac{3}{\log(1/(p^3 + q^3))}(L_n + K_n).$$

Intuitively, this is the range where $\binom{n}{j}(p^j + q^j)^k \to 0$ for all $j \geq 3$, where $\binom{n}{j}(p^j + q^j)^k$ is the expected number of groups of $j$ input-strings having common prefixes of length at least $k$; since $\sum_{j \geq 3} \binom{n}{j}(p^j + q^j)^k \to 0$, all nodes appearing at levels $\geq k$ are most likely only in pairs (see [32] for more precise local limit theorems for $B_{n,k}$).

Let $\tilde{\sigma}_{n,k} := \sqrt{\tilde{V}_k(n) - n\tilde{M}_k(n)^2}$ (see Theorem 7). We will prove, by extending the above de-Poissonization procedure, that

$$\mathbb{E}\exp\left(\frac{B_{n,k} - \tilde{M}_{k}(n)}{\tilde{\sigma}_{n,k}}i\varphi\right) = e^{-\varphi^2/2}\left(1 + O\left(\frac{1 + |\varphi|^3}{\tilde{\sigma}_{n,k}}\right)\right),$$

uniformly for $\varphi = o(\sigma_{n,k}^{1/5})$, which implies (69) by Lévy’s continuity theorem since $\mu_{n,k} \sim \tilde{M}_{k}(n)$ and $\sigma_{n,k} \sim \tilde{\sigma}_{n,k}$ when $\mu_{n,k} \to \infty$. Note that as far as the central limit theorem is concerned, the validity of (71) in the range $\varphi = O(1)$ suffices; observe also that centering $B_{n,k}$ by the exact mean or normalizing $B_{n,k}$ by the exact variance will result in a poorer error term.

Our method of proof of (71) is roughly as follows. We start by deriving a closed-form expression for the bivariate generating function $P_k(z,y) = \sum_{n \geq 0} P_{n,k}(y)z^n/n!$ by using the recurrence (1). We then will apply the Cauchy integral representation to prove (71), for which we need, as in the analytic de-Poissonization used above, a crude estimate for $|P_k(re^{i\theta},e^{i\varphi})|$ for $|\theta|$ away from zero, as well as a more precise local expansion when $|\theta|$ is very close to zero. The proof for the Poisson limit law (70) is similar.

5.1. An exact expression for $P_k(z,y)$. By (1), we have the functional equation

$$P_k(z,y) = P_{k-1}(pz,y)P_{k-1}(qz,y) \quad (k \geq 2)$$

with

$$P_1(z,y) = e^z + (y - 1)z(p(e^{qz} - 1) + q(e^{pz} - 1)) + pq(y - 1)^2z^2.$$

By iterating this functional equation, we obtain

$$P_k(z,y) = \prod_{0 \leq j < k} P_1(p^j q^{k-j - 1} z, y) \left(\frac{k - 1}{j}\right) \quad (k \geq 1).$$

This expression, although explicit, is less transparent from an asymptotic viewpoint.

5.2. A uniform estimate for $|P_k(re^{i\theta}, y)|$. We first prove a uniform bound on $|P_k(re^{i\theta}, y)|$ that is necessary for the proof of Theorem 8.

PROPOSITION 3. Uniformly for $k \geq 1$, $r \geq 0$, $|\theta| \leq \pi$ and $|y| = 1$,

$$|P_k(re^{i\theta}, y)| \leq e^{r - c r \theta^2}$$

for some constant $c > 0$ independent of $k, r$, and $\theta$. 
In order to prove the above proposition we need a lemma.

**Lemma 6.** If $z = re^{i\theta}$, where $r \geq 0$ and $|\theta| \leq \pi$, then

$$|e^z - 1 - z| \leq (e^r - 1 - r)e^{-c_1r\theta^2},$$  \hspace{1cm} (74)

where $c_1 := 2/(3\pi^2)$. On the other hand, if $r \geq r_0$, where $r_0 \approx 1.37$ solves the equation $e^r - r = e^{r/3} + 1$, then

$$|e^z - z| \leq (e^r - r)e^{-c_1r\theta^2/2} \quad (|\theta| \leq \pi).$$  \hspace{1cm} (75)

**Proof.** The first inequality is a special case of Pittel’s inequality (see [65])

$$\left| e^z - \sum_{0 \leq j < m} \frac{z^j}{j!} \right| \leq \left( e^r - \sum_{0 \leq j < m} \frac{r^j}{j!} \right) e^{-2r\theta^2/(\pi^2(m+1))} \quad (r \geq 0; |\theta| \leq \pi).$$

A simple proof of (74) (following [65]) is as follows:

\[
|e^z - 1 - z| = |e^{z/3}| \left| e^{2z/3} - (1 + z)e^{-z/3} \right|
\]

\[
= e^{r \cos(\theta)/3} \left| \sum_{j \geq 2} \frac{z^j}{j!3^j} (2^j + (-1)^j(3j - 1)) \right|
\]

\[
\leq e^{r \cos(\theta)/3} (e^{2r/3} - (1 + r)e^{-r/3}),
\]

since $2^j + (-1)^j(3j - 1) \geq 0$ for $j \geq 2$. Thus (74) follows from (29).

For the proof of inequality (75), we have

\[
|e^z - z| \leq |e^z - 1 - z| + 1
\]

\[
\leq (e^r - 1 - r)e^{-c_1r\theta^2} + 1
\]

\[
\leq (e^r - r)e^{-c_1r\theta^2/2},
\]

since the last inequality is equivalent to

\[
1 - e^{-c_1r\theta^2} \leq (e^r - r)e^{-c_1r\theta^2/2} \left( 1 - e^{-c_1r\theta^2/2} \right),
\]

or $e^{-c_1r\theta^2} + 1 \leq e^r - r$, which follows from our choice of $r$ in view of the inequalities $e^{-c_1r\theta^2} + 1 \leq e^{r/3} + 1 \leq e^r - r$. \hspace{1cm} \Box

**Proof of Proposition 3.** We separate the proof into two cases: $r \leq r_0$ and $r \geq r_0$, where we recall that $r_0 \approx 1.37$ solves the equation $e^r - r = e^{r/3} + 1$. In the first case, we use the expansion

\[
P_1(z, y) = 1 + z + \frac{z^2}{2} (1 - 2pq(1 - y^2)) + \sum_{j \geq 2} \frac{z^j}{j!} \left( 1 - \frac{1}{2} (pq)^j + q(pq)^{j-1} \right)(1 - y),
\]

which yields

\[
|P_1(re^{i\theta}, e^{ic})| \leq |1 + re^{i\theta}| + \sum_{j \geq 2} \frac{r^j}{j!}
\]

\[
\leq e^r - \frac{2r\theta^2}{\pi^2(1 + r)}
\]

\[
\leq e^{r - c_2r\theta^2},
\]

(76)
uniformly for $0 \leq r \leq r_0$ and $|\theta| \leq \pi$, where we used again (29) and $c_2 := 2/(\pi^2(1 + r_0)^2 e^r)$.

Assume now $r \geq r_0$. We can write $P_1(z, y)$ as follows:

$$P_1(z, y) = a_1(pz)a_1(qz) + z + (qza_2(pz) + pza_2(qz))y + pqz^2y^2,$$

where $a_1(z) := e^z - z$ and $a_2(z) := e^z - 1 - z$. Note that $P_1(z, 1) = e^z$. By applying the two inequalities (74) and (75), we have

$$\left| P_1\left(re^{i\theta}, e^{i\varphi}\right) \right| \leq a_1(pr)a_1(qr)e^{-c_1r^2/2} + r + qra_2(pr)e^{-c_1qr^2} + pr\theta^2 + pqr^2,$$

$$\leq \left( e^r - r - pqr^2 \right) e^{-c_1qr^2} + r + pqr^2$$

(77)

the last inequality following from an argument similar to the proof of (75). Indeed, it is equivalent to

$$\left( r + pqr^2 \right) \left( e^{c_1qr^2/2} + 1 \right) \leq e^r,$$

but the left-hand side is less than $\left( r + r^2/4 \right)\left( e^{r/6} + 1 \right)$, which is in turn less than $e^r$ for $r \geq 0.99$.

Collecting the two inequalities (76) and (77), we obtain

$$\left| P_1\left(re^{i\theta}, e^{i\varphi}\right) \right| \leq e^{e^r - cr^2/2} \quad (c = \min\{c_1, c_2\}),$$

uniformly for $r \geq 0$ and $|\theta| \leq \pi$. This implies (73) by (72).

5.3. Local expansion of $P_k\left(re^{i\theta}, e^{i\varphi}\right)$. Recall that $\theta_0 := n^{-2/5}$ and $\rho_0$ is defined in (59).

Proposition 4. Assume that $\mu_{n,k} \to \infty$. Then uniformly for $|\theta| \leq \theta_0$ and $\varphi = o(\sigma_{n,k}^{-2/3})$

(78)

$$P_k\left(ne^{i\theta}, e^{i\varphi}\right) = \exp\left( n - \frac{n}{2} \theta^2 + \hat{M}_k(n)i\varphi - n\hat{M}_k(n)\varphi \theta - \frac{\hat{V}_k(n)}{2} \varphi^2 + O(E_4) \right),$$

where

$$E_4 := n|\theta|^3 + \rho_0^2\sigma_{n,k}^2|\varphi|^2 + \rho_0\sigma_{n,k}^2|\theta|^2 + \sigma_{n,k}^2|\varphi|^3.$$

Proof. Define

$$Q(z, y) := \log e^{-z}P_1(z, y) = \log \left( 1 + a_3(z)(y - 1) + a_4(z)(y - 1)^2 \right),$$

where $a_3(z) := pze^{-pz} + qze^{-qz} - ze^{-z}$ and $a_4(z) := pqz^2e^{-z}$. Let

$$Q_k(z, y) := \sum_{0 \leq j < k} \binom{k - 1}{j} \frac{\hat{M}e^{-jz} + \hat{V}_k(n)}{2} \varphi^2.$$
Then since $\mu_{n,k} \to \infty$, we need only consider $k \geq k_0$. To that purpose, we start from the expansion

$$Q(z,y) = \begin{cases} \frac{pq(y^2 - 1)}{2} + O(|y - 1||z|^3) & \text{as } z \to 0, \\ q(y - 1)ze^{-q^2} (1 + O(e^{-|p-q|^R(z)})) & \text{as } z \to \infty, |\arg(z)| \leq \varepsilon. \end{cases}$$

By (79), we have

$$Q_k(z,y) = \frac{1}{2\pi i} \int_{(\rho)} z^{-s}Q^*(s,y)(p^{-s} + q^{-s})^{k-1}ds,$$

where $\rho > -2$ and $Q^*(s,y) := \int_0^\infty z^{s-1}Q(z,y)dz$ is well defined for $\Re(s) > -2$. Note that

$$Q(z,y) = a_3(z)(y - 1) + \frac{2a_4(z) - a_3(z)^2}{2} (y - 1)^2 + \tilde{Q}(z,y)(y - 1)^3,$$

where by Taylor’s remainder formula

$$\tilde{Q}(z,y) := \int_0^1 (1 - t)^2(a_3(z) + 2a_4(z)(y - 1)t)$$

$$\times \frac{(a_3(z))^2 - 3a_4(z) + a_3(z)a_4(z)(y - 1)t + a_4(z)^2(y - 1)^2t^2)}{(1 + a_3(z)(y - 1)t + a_4(z)(y - 1)^2t^2)^3} dt.$$

The exact form is of less importance here; we need instead the estimates $Q(z,y) = O(|z|^3) = O(|z|^2)$ as $z \to 0$ and

$$\tilde{Q}(z,y) = O \left( |z|^3e^{-3q\Re(z)} \right) = O \left( |z|e^{-q\Re(z)} \right)$$

as $z \to \infty$ in the sector $\{ z : |\arg(z)| \leq \varepsilon \}$. This expansion gives

$$Q_k(z,y) = \tilde{M}_k(z)(y - 1) + \frac{\tilde{V}_k(z) - \tilde{M}_k(z)}{2} (y - 1)^2 + \tilde{Q}_k(z,y)(y - 1)^3,$$

where

$$\tilde{Q}_k(z,y) := \sum_{0 \leq j < k} \binom{k-1}{j} \tilde{Q}(p^jq^{k-1-j}z,y).$$

An application of Lemma 8 presented in Appendix C yields, with $z = ne^{i\theta}$,

$$Q_k(z,y) = \tilde{M}_k(z)(y - 1) + \frac{\tilde{V}_k(z) - \tilde{M}_k(z)}{2} (y - 1)^2 + O \left( |y - 1|^3|\tilde{M}_k(ne^{i\theta})| \right),$$

where the $O$-term holds uniformly for $|\theta| \leq \varepsilon$ and $|y - 1| = o(1)$. Since $\sigma_{n,k}^2 = \Theta(\mu_{n,k}) \to \infty$, this leads to (78) by expansions of $\tilde{M}_k(ne^{i\theta})$ and $\tilde{V}_k(ne^{i\theta})$ at $\theta = 0$, using the estimates (60) and (68). This completes the proof of Proposition 4. \Box

5.4. Proof of Theorem 8. We are now ready to prove Theorem 8.
Proof of the central limit theorem (69). By Cauchy’s integral formula and the two estimates (73) and (78), we have, similar to (25),

\[ E(e^{B_n,k\varphi}) = \frac{n!}{2\pi i} \int_{|z|=n} z^{-n-1} P_k(z, y) dz \]

\[ = \frac{n!}{2\pi} e^{n+\bar{N}_k(n)i\varphi-V_k(n)\varphi^2/2} \]

\[ \times \int_{-\theta_0}^{\theta_0} e^{-n\varphi^2/2-n\bar{N}_k(n)\varphi^2} (1 + O(E_4)) d\varphi + O\left(n^{-1/10} e^{-cn^{1/5}}\right), \]

since \( E_4 \to 0 \) in the range of integration and when \( \varphi = o(\sigma_k^{-4/5}) \). Applying Stirling’s formula, extending the integration limits to \( \pm \infty \), and making the change of variables \( \theta \mapsto \theta n^{1/2} \), we obtain

\[ E(e^{B_n,k\varphi}) = \frac{e^{\bar{N}_k(n)i\varphi-\sigma_k^2\varphi^2/2}}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-(\theta+i\varphi)\bar{N}_k(n)\varphi^2/2} \]

\[ \times \left(1 + O\left(\frac{1+|\theta|^3}{\sqrt{n}} + \frac{|\theta|^2}{n} \sigma_k^2 |\varphi| + \frac{|\theta|}{n} \sigma_k^2 |\varphi|^2 + \sigma_k^2 |\varphi|^3\right)\right) d\theta, \]

uniformly in \( \varphi \). A straightforward evaluation of the integral gives (71). This completes the proof of (69).

Proof of the Poisson limit theorem (70). The proof of (70) is similar to the previous proof but proceeds slightly differently. We first show that

\[ (81) \quad Q_k(ne^{it}, y) := \log e^{-z} P_k(z, y) = \lambda_0(y^2 - 1)e^{2i\theta} + O\left(|y - 1|n^{-e(p)}\right), \]

uniformly for \( |y| = 1 \) and \( |\theta| \leq \varepsilon \), where \( e(p) := 2\log(p^3 + q^3)/\log(p^2 + q^2) - 3 \in (0,1) \) for \( p \in (1/2,1) \).

This follows from the Mellin inversion integral (80) since the Mellin transform \( Q_s(s, y) \) has a simple pole at \( s = -2 \) with residue \( pq/(y^2 - 1) \) and can be meromorphically continued into the whole \( s \)-plane. Indeed, by moving the line of integration of the integral in (80) to \( \Re(s) = -3 - \varepsilon \), we obtain

\[ Q_k(ne^{it}, y) = \lambda_0(y^2 - 1)e^{2i\theta} + O\left(|y - 1|n^3(p^3 + q^3)^k\right), \]

whenever \( |\theta| \leq \pi/2 - \varepsilon \) and

\[ k \geq \frac{L_n + K_n}{\log((p^2 + q^2)/(p^3 + q^3))}. \]

Since \( \mu_{n,k} = \Theta(1) \), we know that \( k = \alpha_3 L_n + O(1) \), and for such values of \( k \), we have \( n^3(p^3 + q^3)^k = \Theta(n^{-e(p)}) \). Thus (81) follows.

By (81) and the same choice of \( \theta_0 \) and (73), we then deduce that

\[ E(e^{B_n,k\varphi}) = \frac{e^{\lambda_0(e^{2i\varphi}-1)}}{\sqrt{2\pi}} \int_{-n^{1/10}}^{n^{1/10}} e^{-\theta^2/2} \left(1 + O\left(n^{-e(p)}|\varphi|\right)\right) \]

\[ \times \left(1 + \frac{12\lambda_0(e^{2i\varphi}-1)i\theta - i\theta^3}{6\sqrt{n}} + O\left(\frac{1 + \lambda_0|\varphi|^2 + \theta^6}{n}\right)\right) d\theta \]

\[ = e^{\lambda_0(e^{2i\varphi}-1)} (1 + O(E_5)), \]
uniformly for $|\varphi| \leq \pi$, where $E_5 := |\varphi|n^{-\varepsilon(p)} + (1 + \lambda_0|\varphi|)n^{-1}$. Thus

$$\mathbb{P}\left(\frac{B_{n,k}}{2} = m\right) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{-im\varphi + \lambda_0(e^{i\varphi} - 1)} (1 + O(E_5)) \, d\varphi,$$

from which the even case in (70) follows since, by (50), $\mu_{n,k} \sim 2\lambda_0$. The odd case is similar.

Remark. Note that $\lambda_0$ is periodic in nature since $k = \alpha_3 L_n + O(1) \in \mathbb{Z}$; indeed, we can write

$$k = |\alpha_3 L_n| + \ell = \alpha_3 L_n + \ell - \{\alpha_3 L_n\} \quad (\ell \in \mathbb{Z}),$$

so that

$$n^2(p^2 + q^2)k = \exp\left(-\frac{2}{\alpha_3} (\ell - \{\alpha_3 L_n\})\right).$$

This is why we did not state the Poisson convergence (70) in the usual form: if $\lambda_0 \to \lambda < \infty$, then $B_{n,k}$ converges in distribution to $2\text{Po}(\lambda)$, where $\text{Po}(\lambda)$ denotes a Poisson variate with parameter $\lambda$.

6. The internal profile. We consider the internal profile in this section. All asymptotic results follow the same footsteps as in the proof we used for $B_{n,k}$; details will thus be omitted. The main differences are that $\mathbb{E}(I_{n,k})$ and $\mathbb{V}(I_{n,k})$ are not of the same order for all ranges of $k$, and $I_{n,k}$ assumes both odd and even values when $k = \alpha_3 L_n + O(1)$. These are intuitively clear since most levels close to the root are full and internal nodes do not necessarily appear in pairs near the fringes of the tree.

Let $P_{n,k}^{[I]}(y) = \mathbb{E}(y^{I_{n,k}})$ be the probability generating function of $I_{n,k}$. Then

$$P_{n,k}^{[I]}(y) = \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j} P_{j,k-1}^{[I]}(y) P_{n-j,k-1}^{[I]}(y) \quad (n \geq 2; k \geq 1),$$

with the initial conditions

$$P_{0,k}^{[I]}(y) = \begin{cases} y & \text{if } n \geq 2 \text{ and } k = 0, \\ 1 & \text{if } n \leq 1 \text{ and } k \geq 0. \end{cases}$$

From this, we obtain, defining $P_{k}^{[I]}(z,y) := \sum_{n} P_{n,k}^{[I]}(y)z^n/n!$,

$$P_{k}^{[I]}(z,y) = \prod_{0 \leq j \leq k} \mathbb{P}_{0}^{[I]}(p^j q^{k-j} z, y)^{(k)} \quad (k \geq 0),$$

with $\mathbb{P}_{0}^{[I]}(z,y) = ye^z + (1 - y)(1 + z)$. This suggests that we consider

$$\bar{I}_{n,k} := 2^k - I_{n,k},$$

so that the bivariate generating function $P_{k}^{[I]}(z,y) := \sum_{n} P_{n,k}^{[I]}(y)z^n/n!$ is given by

$$P_{k}^{[I]}(z,y) = \prod_{0 \leq j \leq k} \mathbb{P}_{0}^{[I]}(p^j q^{k-j} z, y)^{(k)} \quad (k \geq 0),$$

with $\mathbb{P}_{0}^{[I]}(z,y) = e^z + (y^{-1} - 1)(1 + z)$. 
6.1. Expected internal profile. We state without proof the asymptotics of \( \mathbb{E}(I_{n,k}) \) in this subsection. By (82) or (83), we deduce that the Poisson generating function
\[
\tilde M_k^{[l]}(z) := e^{-z} \sum_{n \geq 0} \frac{\mathbb{E}(I_{n,k})}{n!} z^n
\]
satisfies
\[
\tilde M_k^{[l]}(z) = 2^k - \sum_{0 \leq j \leq k} \binom{k}{j} \tilde M_0^{[j]}(p^j q^{k-j} z)
\]

where \( \rho > 0 \) and \( \tilde M_0^{[j]}(z) = (1 + z)e^{-z} \). Thus, in particular,
\[
\mathbb{E}(I_{n,k}) = 2^k - \sum_{0 \leq j \leq k} \binom{k}{j} (1 + p^j q^{k-j}(n-1)) (1 - p^j q^{k-j})^{n-1}.
\]

Due to the presence of \( 2^k \) or the simple pole at \( s = 0 \) in (85), we have an additional phase transition for \( \mathbb{E}(I_{n,k}) \) at \( \rho = 0 \) or, equivalently, at \( k \sim \alpha_0 L_n \), where
\[
\alpha_0 := \frac{2}{\log(1/p) + \log(1/q)}.
\]

We now list asymptotic approximations of \( \mathbb{E}(I_{n,k}) \) for various ranges of \( k \) (without proofs since they follow the same lines as the derivations presented above for the external profile).

Asymptotics of \( \mathbb{E}(I_{n,k}) \) when \( 1 \leq k \leq \alpha_1(1 + o(1))L_n \). Since
\[
\tilde M_k^{[l]}(z) = 2^k - (1 + pz)e^{-pz} + (1 + qz)e^{-qz} = 2^k - qze^{-qz} (1 + O(|z|^{-1}))
\]
as \( |z| \to \infty \) in the sector \( |\arg(z)| \leq \pi/2 - \varepsilon \), we see immediately that in this range
\[
\mathbb{E}(I_{n,k}) = 2^k - \mathbb{E}(B_{n,k})(1 + o(1)),
\]
uniformly in \( k \).

Asymptotics of \( \mathbb{E}(I_{n,k}) \) when \( \alpha_1(L_n - LLL_n + K_n) \leq k \leq \alpha_0(L_n - K_n \sqrt{n}) \). By applying the saddle-point method to the Mellin inversion integral in (85) and then de-Poissonizing, we deduce that in this range
\[
\mathbb{E}(I_{n,k}) = 2^k - G_3 \left( \rho; \log_{p/q} p^k n \right) \frac{n^{-\rho} (p^{-\rho} + q^{-\rho})^k}{\sqrt{2\pi \beta_2(\rho) k}} \left( 1 + O \left( \frac{1}{k(p/q)^\rho} + \frac{1}{k^2} \right) \right),
\]
where \( \rho = \rho(n, k) > 0 \) satisfies the saddle-point equation (36), \( \beta_2(\rho) \) is the same as in (37), and
\[
G_3(\rho; x) = \sum_{j \in \mathbb{Z}} (\rho + 1 + it_j) \Gamma(\rho + it_j) e^{-2j\pi ix},
\]
where \( t_j := 2j\pi/\log(p/q) \).
Asymptotics of $\mathbb{E}(I_{n,k})$ when $k = \alpha_0(L_n + o(L_n^{2/3}))$. In this range, we write

$$k = \alpha_0(L_n + \xi \sqrt{\alpha_0 \beta_2(0)L_n}),$$

where $\alpha_0 \beta_2(0) = 2(\log(1/p) + \log(1/q))/\log(p/q)^2$ and $\xi = o(L_n^{1/6})$. The same uniform asymptotic analysis we used for proving (53) gives

$$\mathbb{E}(I_{n,k}) = 2^k\Phi(-\xi) \left(1 + O\left(\frac{1}{\sqrt{L_n}}\right)\right),$$

uniformly in $\xi$, where $\Phi(x)$ denotes the standard normal distribution function.

Asymptotics of $\mathbb{E}(I_{n,k})$ when $\alpha_0(L_n + K_n \sqrt{L_n}) \leq k \leq \alpha_2(L_n - K_n \sqrt{L_n})$. The same saddle-point method and de-Poissonization procedure yield

(87)

$$\mathbb{E}(I_{n,k}) = G_3 \left(\rho; \log_p q^k n\right) n^{-p}(p^{-p} + q^{-q})^k \left(1 + O\left(\frac{1}{k(p/q)^p} + \frac{1}{k(p+2)^2}\right)\right),$$

with $\rho$, $\beta_2(\rho)$, and $G_3$ as defined above.

Asymptotics of $\mathbb{E}(I_{n,k})$ when $k = \alpha_2(L_n + o(L_n^{2/3}))$. In this case, we write

$$k = \alpha_0(L_n + \xi \sqrt{\alpha_2 \beta_2(-2L_n)},$$

and we have

$$\mathbb{E}(I_{n,k}) = \frac{1}{2} \Phi(\xi)n^2(p^2 + q^2)^k \left(1 + O\left(\frac{1 + \xi^2}{\sqrt{L_n}}\right)\right),$$

uniformly for $\xi = o(L_n^{1/6})$.

Asymptotics of $\mathbb{E}(I_{n,k})$ when $k \geq \alpha_2(L_n + K_n \sqrt{L_n})$. In this case, the simple pole at $s = -2$ in the integrand of (85) dominates, and we have

$$\mathbb{E}(I_{n,k}) = \frac{1}{2} n^2(p^2 + q^2)^k \left(1 + O\left(K_n^{-1}e^{-K_n^2/2+O(K_n^2L_n^{-1/2})}\right)\right)$$

as $n \to \infty$.

6.2. Asymptotics of $\mathbb{V}(I_{n,k})$. Since $\mathbb{V}(I_{n,k}) = \mathbb{V} (\bar{I}_{n,k})$, we can apply the same analysis used for proving Theorem 7 to derive asymptotic approximations to $\mathbb{V}(I_{n,k})$.

The auxiliary function we need is

$$\tilde{V}_k^{[l]}(z) := e^{-z} \sum_{n \geq 0} \frac{\mathbb{E}(I_{n,k})}{n!} z^n - \left(e^{-z} \sum_{n \geq 0} \frac{\mathbb{E}(I_{n,k})}{n!} z^n\right)^2,$$

which satisfies

(88)

$$\tilde{V}_k^{[l]}(z) = \sum_{0 \leq j \leq k} \binom{k}{j} \tilde{V}_0^{[l]}(p^j q^{k-j} z) \quad (k \geq 0),$$

where $\tilde{V}_0^{[l]}(z) = (1 + z) e^{-z} (1 - (1 + z) e^{-z})$. Thus we have

$$\tilde{V}_k^{[l]}(z) = \frac{1}{2\pi i} \int_{(\rho)} z^{-s} (s+1) \Gamma(s) (1 - 2^{-s} - s2^{-s-2}) (p^{-s} + q^{-s})^k ds,$$

where $\rho > -2$. 

Asymptotics of $\mathbb{V}(I_{n,k})$ when $1 \leq k \leq \alpha_1(1 + o(1))L_n$. In this range, we have

$$\mathbb{V}(I_{n,k}) \sim \mathbb{V}(B_{n,k}) \sim \mathbb{E}(B_{n,k}).$$

Asymptotics of $\mathbb{V}(I_{n,k})$ when $\alpha_1(L_n - \text{LLL}n + K_n) \leq k \leq \alpha_2(L_n - K_n\sqrt{L_n})$. We have

$$\mathbb{V}(I_{n,k}) = G_4\left(\rho; \log_{p/q}P^k n\right) \frac{n^{-\rho}(p^{-\rho} + q^{-\rho})^k}{\sqrt{2\pi\beta_2(\rho)\rho}} \left(1 + O\left(\frac{1}{k(p/q)^\rho} + \frac{1}{k(\rho + 2)^2}\right)\right),$$

where $\rho = \rho(n, k) > -2$ satisfies the saddle-point equation (36) and

$$G_4(\rho; x) = \sum_{j \in \mathbb{Z}}(\rho + 1 + i\ell x)\Gamma(\rho + i\ell x) \left(1 - 2^{-\rho - i\ell} - (\rho + i\ell)2^{-\rho - 2 - i\ell}\right)e^{-2\pi \ell x}.$$

Asymptotics of $\mathbb{V}(I_{n,k})$ when $k \geq \alpha_2(L_n + K_n\sqrt{L_n})$. In this case, the simple pole at $s = -2$ again dominates, and we have

$$\mathbb{V}(I_{n,k}) \sim \mathbb{E}(I_{n,k}).$$

Observe that, unlike for the external profile, the variance of the internal profile is asymptotically equivalent to the mean of the internal profile near the height of a trie.

From these asymptotic estimates and from Chebyshev’s inequality, we see that $I_{n,k}/\mathbb{E}(I_{n,k}) \to 1$ in probability if $\mathbb{E}(I_{n,k}) \to \infty$; see [15].

### 6.3. Limiting distributions

The same limiting Gaussian–Poisson behavior for $B_{n,k}$ holds for $I_{n,k}$. We state formally our main result for the internal profile in the following theorem. The proof is indeed simpler than that for Theorem 8 since the base function $P_{0,1}(z, y)$ has a simpler form than $P_{0,1}(z, y)$.

**Theorem 9.** (i) If $\mathbb{V}(I_{n,k}) \to \infty$, then

$$\frac{I_{n,k} - \mathbb{E}(I_{n,k})}{\sqrt{\mathbb{V}(I_{n,k})}} \xrightarrow{d} \mathcal{N}(0, 1).$$

(ii) If $\mathbb{V}(I_{n,k}) = \Theta(1)$, then, with $\lambda_1 := n^2(p^2 + q^2)/2$,

$$\mathbb{P}(I_{n,k} = m) = \frac{\lambda_1^m}{m!} e^{-\lambda_1} + o(1)$$

(89)

for all $m \geq 0$.

The theorem states that asymptotic normality (in the sense of convergence in distribution) holds as long as

$$[\hat{k}] \leq k \leq \alpha_3 L_n - K_n$$

for any sequence $K_n \to \infty$, where $\hat{k}$ is defined in (58).

On the other hand, $I_{n,k}$ is asymptotically Poisson distributed when $k = \alpha_3 L_n + O(1)$. A result related to (89) was given in [65] by a method of moments, as a key step in deriving the asymptotic distribution of the height.

### 7. Profiles under the unbiased Bernoulli model

All exact expressions we have derived up to now, as well as most asymptotic approximations, also hold when $p = q = 1/2$. The major difference is reflected by the fact that $\alpha_1 = \alpha_2$ (see Figure 2), so that the saddle-point range between $\alpha_1$ and $\alpha_2$ does not exist, and most of the analysis we give above becomes much simpler. For simplicity of presentation, we omit all error terms in our asymptotic estimates.
Expected external profile. By (8), the Poisson generating function of \( E(B_{n,k}) \) is given exactly by

\[
\tilde{M}_k(z) = z \left( e^{-z/2^k} - e^{-z/2^{k-1}} \right) \quad (k \geq 1).
\]

From this we deduce, by our de-Poissonization procedures, that

\[
E(B_{n,k}) \sim \begin{cases} 
  n (1 - 2^{-k})^{n-1} & \text{if } 2^{-k}n \to \infty, \\
  \tilde{M}_k(n) & \text{if } 4^{-k}n \to 0,
\end{cases}
\]

where the condition \( 4^{-k}n \to 0 \) is due to the properties that

\[
\tilde{M}_k(z) = O \left( 2^{-k\ell} |\tilde{M}_k(z)| \right) \quad \left( |\arg(z)| \leq \pi/2 - \epsilon \right)
\]

and \( 2^{-k} = o(n^{-1/2}) \); see Proposition 1 and compare with (61). In particular,

\[
E(B_{n,k}) \sim \begin{cases} 
  2^{-k} n (1 - e^{-t}) & \text{if } 2^{-k}n \to t \in (0, \infty), \\
  2^{-k} n^2 & \text{if } 2^{-k}n \to 0.
\end{cases}
\]

Note that these approximations can also be easily derived by the exact formula

\[
E(B_{n,k}) = n (1 - 2^{-k})^{n-1} - n (1 - 2^{1-k})^{n-1},
\]

by (90) or (10). But such an elementary approach becomes messier for the calculation of the variance. Also

\[
\max_k E(B_{n,k}) \sim \frac{n}{4},
\]

which is reached when \( k \sim \log_2 n - 1 \).

Expected internal profile. In a similar manner, we have, by (84),

\[
\tilde{M}_k^{[I]}(z) = 2^k - (2^k + z) e^{-z/2^k} \quad (k \geq 0).
\]

Therefore, the expected internal profiles satisfy

\[
E(I_{n,k}) \sim \begin{cases} 
  2^k n \left( 1 - 2^{-k} \right)^{n-1} & \text{if } 2^{-k}n \to \infty, \\
  \tilde{M}_k^{[I]}(n) & \text{if } 4^{-k}n \to 0.
\end{cases}
\]

Consequently,

\[
E(I_{n,k}) \sim \begin{cases} 
  2^k \left( 1 - (1 + t) e^{-t} \right) & \text{if } 2^{-k}n \to t \in (0, \infty), \\
  2^{-k-1} n^2 & \text{if } 2^{-k}n \to 0.
\end{cases}
\]

Note that

\[
E(I_{n,k}) = 2^k \left( 1 - (1 - 2^{-k})^n \right) - n (1 - 2^{-k})^{n-1}
\]

and

\[
\max_k E(I_{n,k}) \sim c_3 n,
\]

where \( c_3 \approx 0.298 \) denotes the maximum value achieved by the function \( (1 - (1 + x) e^{-x})/x \) for \( x \in \mathbb{R}^+ \).
Asymptotics of the variances. Similarly, by (63) and (88), we have

\[ \tilde{V}_k(z) = z \left( e^{-z/2^k} - e^{-z/2^{k-1}} \right) + 2^{-k} z^2 \left( e^{-z/2^k} - e^{-z/2^{k-1}} \right)^2, \]

\[ \tilde{V}_k^{[l]}(z) = (2^k + z) e^{-z/2^k} - 2^k (1 + 2^{-k})^2 e^{-z/2^{k-1}}; \]

accordingly, if \( n/2^k \to \infty \), then

\[ \mathbb{V}(B_{n,k}) \sim \mathbb{V}(I_{n,k}) \sim \mathbb{E}(B_{n,k}) \sim n \left( 1 - 2^{-k} \right)^{n-1}, \]

and if \( n/4^k \to 0 \), then

\[ \mathbb{V}(B_{n,k}) \sim \tilde{V}_k(n) \quad \text{and} \quad \mathbb{V}(I_{n,k}) \sim \tilde{V}_k^{[l]}(n), \]

uniformly in \( k \). These approximations imply that

\[ (94) \quad \mathbb{V}(B_{n,k}) \sim \begin{cases} ne^{-t} \left( 1 - (1 + t)e^{-t} + 2te^{-2t}(2 - e^{-t}) \right) & \text{if } 2^{-k}n \to t \in (0, \infty), \\ 2\mathbb{E}(B_{n,k}) \sim 2^{1-k}n^2 & \text{if } 2^{-k}n \to 0 \end{cases} \]

and

\[ \mathbb{V}(I_{n,k}) \sim \begin{cases} 2^k(1+t)e^{-t} \left( 1 - (1 + t)e^{-t} \right) & \text{if } 2^{-k}n \to t \in (0, \infty), \\ \mathbb{E}(I_{n,k}) \sim 2^{1-k}n^2 & \text{if } 2^{-k}n \to 0. \end{cases} \]

Limiting distributions. Both Theorems 8 and 9 (asymptotic normality of \( B_{n,k} \) and \( I_{n,k} \), respectively) hold when \( p = q = 1/2 \) by the same method of proof. Note that both bivariate generating functions become simpler (see (72) and (83));

\[ P_k(z, y) = \left( e^{z/2^{k-1}} + (y - 1) e^{z/2^k} - 1 \right) + (y - 1) \left( z/2^k \right)^2, \]

\[ P_k^{[l]}(z, y) = \left( ye^{z/2^k} + (1 - y) \left( 1 + \frac{z}{2^k} \right) \right)^2. \]

Observe that, as \( n \to \infty \), \( \mathbb{E}(B_{n,k}) \to \infty \) iff \( \mathbb{V}(B_{n,k}) \to \infty \) iff \( \mathbb{V}(I_{n,k}) \to \infty \) iff

\[ (95) \quad \frac{1}{\log 2} \left( L_n - LL_n + \frac{K_n}{I_n} \right) \leq k \leq \frac{2}{\log 2} \left( L_n - K_n \right) \]

for any sequence \( K_n \to \infty \) with \( n \); compare Theorem 5 for the asymmetric case.

**Theorem 10.** (i) If \( k \) lies in the range (95), then

\[ \frac{B_{n,k} - \mathbb{E}(B_{n,k})}{\sqrt{\mathbb{V}(B_{n,k})}} \overset{d}{\to} \mathcal{N}(0,1), \quad \frac{I_{n,k} - \mathbb{E}(I_{n,k})}{\sqrt{\mathbb{V}(I_{n,k})}} \overset{d}{\to} \mathcal{N}(0,1). \]

(ii) If \( k = (2(L_n + O(1))/\log 2 \to k \), then with \( \lambda_2 := 2^{-k-1}n^2 \),

\[ \mathbb{P}(B_{n,k} = 2m) = \frac{\lambda_2^m}{m!} e^{-\lambda_2} + o(1), \quad \mathbb{P}(B_{n,k} = 2m + 1) = o(1), \]

\[ \mathbb{P}(I_{n,k} = m) = \frac{\lambda_2^m}{m!} e^{-\lambda_2} + o(1), \]

uniformly for \( m \geq 0 \).

Note that when \( p = q \), \( \lambda_0 = \lambda_1 = \lambda_2 \).
8. Applications of results. In this section, we briefly discuss a few properties of some shape characteristics of random tries, as implied either by our results or by our approaches. We consider only depth, height, shortest path, fill-up level, width, and right-profile.

Depth. The distribution of the depth $D_n$ is given by $P(D_n = k) = \mu_{n,k}/n$. Our asymptotic approximations for $\mu_{n,k}$ give very precise results for the distribution of $D_n$. First consider the case when $p \neq q$. By definition, we see that the result (4) for the limiting behaviors of $\log \mu_{n,k}/\log n$ also describes those of $-1 + \log P(D_n = k)/\log n$, or essentially the large deviations of the distribution of $D_n$.

Furthermore, (43) can be regarded as a local limit theorem for $D_n$. Indeed, we have, for $k = h^{-1}(L_n + x\sqrt{h^{-1}\beta_2(-1)L_n})$, where $h := p\log(1/p) + q\log(1/q)$ is the entropy rate,

$$P(D_n = k) = G_1 \left(-1; \log_{p/q} p^k n\right) \frac{e^{-x^2/2}}{\sqrt{2\pi} \sqrt{V(D_n)}} \left(1 + O\left(\frac{|x|^3}{\sqrt{n}}\right)\right),$$

uniformly for $x = o(L_n^{1/6})$, where $V(D_n) \sim (h_2 - h^2)/h^3 \log n$, with $h_2 := p\log^2 p + q\log^2 q$ (see [33, 76]), is also rederived below in (97). Because of the appearance of the uncommon periodic function $G_1$, we see that $D_n$ satisfies a central limit theorem but not a local limit theorem (of the usual form). It can be shown that the right-hand side indeed sums (over all $k$) asymptotically to 1. The result (96) is new.

If $p = q$, then, by the exact formula (92), we have

$$P(D_n = k) = \left(1 - 2^{-k}\right)^{n-1} - \left(1 - 2^{1-k}\right)^{n-1},$$

which implies that

$$P(D_n = \lfloor \log_2 n \rfloor + \ell) = \left(e^{-2^{-\ell+\lfloor \log_2 n \rfloor}} - e^{-2^{1-\ell+\lfloor \log_2 n \rfloor}}\right) \left(1 + O\left(n^{-1}\right)\right),$$

uniformly for $\ell \in \mathbb{Z}$, where $\{x\}$ denotes the fractional part of $x$.

On the other hand, if one is interested in the cumulative distribution functions or tail probabilities, then, by (6) and by partial summation,

$$P(D_n \leq k) = (n - 1)! [z^n] \frac{e^z}{2\pi i} \int_{(\rho)} z^{-s} \Gamma(s + 1) \left(p^{-s} + q^{-s}\right)^k \, ds$$

for $k \geq 1$, where $\rho > -1$. Equivalently, by (11), we have (see [35])

$$P(D_n \leq k) = \frac{1}{2\pi i} \int_{(\rho)} \frac{\Gamma(n)\Gamma(s + 1)}{\Gamma(n + 1 + s)} \left(p^{-s} + q^{-s}\right)^k \, ds,$$

where $\rho > -1$. Asymptotics of such integrals can be treated by our approaches, which give not only the central limit theorem of $D_n$ with convergence rate (since there is a simple pole at $s = -1$) but also precise estimates for tail probabilities. Indeed, we have

$$P\left(D_n \leq h^{-1}(L_n + x\sqrt{h^{-1}\beta_2(-1)L_n})\right) = \Phi(x) \left(1 + O\left(\frac{1 + |x|^3}{\sqrt{L_n}}\right)\right),$$
uniformly for \( x = o(L_n^{1/6}) \), as already shown in [33, 35] (but without rate). Furthermore,

\[
-\frac{\log \mathbb{P}(D_n \leq \alpha L_n)}{\log n} \to \rho' + 1 - \alpha \log(p^{-\rho'} + q^{-\rho'}) \quad (\alpha_1 \leq \alpha \leq h^{-1}),
\]

\[
-\frac{\log \mathbb{P}(D_n \geq \alpha L_n)}{\log n} \to \begin{cases} 
\rho' + 1 - \alpha \log(p^{-\rho'} + q^{-\rho'}) & \text{if } h^{-1} \leq \alpha \leq \alpha_2, \\
-1 - \alpha \log(p^2 + q^2) & \text{if } \alpha_2 \leq \alpha \leq \alpha_3,
\end{cases}
\]

both tails being asymptotic to \(-1\) for smaller and larger \( \alpha \), respectively, where \( \rho' \) is given in (42). These results imply, in particular, that \( \mathbb{E}(D_n) \sim L_n/h \) and

\[
\mathbb{V}(D_n) \sim \beta_2(-1)h^{-3}L_n = \frac{pq\log^2(p/q)}{(p \log(1/p) + q \log(1/q))^3} L_n = \frac{h_2 - h^2}{h^3} L_n,
\]

where \( h_2 := p \log^2 p + q \log^2 q \); see [13, 76]. Note that the constant on the right-hand side becomes zero when \( p = q \).

**Width.** The width of tries \( W_n \) is defined to be \( W_n := \max_k I_{n,k} \), or the size of the most abundant level(s). As a natural lower bound for \( \mathbb{E}(W_n) \), we consider \( \max_k \mathbb{E}(I_{n,k}) \). By (87) and a similar analysis for (43), we have, when \( p \neq q \),

\[
\mathbb{E}(I_{n,k}) = \sqrt{k} G_3\left(-1; \log(p/q)p^k n\right) \frac{n}{\log(p/q)\sqrt{2\pi pq}} \times \frac{n}{\sqrt{L_n}} \left(1 + \mathcal{O}(L_n^{-1/2})\right),
\]

uniformly for \( k = L_n/h + \mathcal{O}(1) \). This approximation, together with the estimates for \( \mathbb{E}(I_{n,k}) \) in other ranges given in section 6.1, yields

\[
\mathbb{E}(W_n) \geq \max_k \mathbb{E}(I_{n,k}) = \Theta(nL_n^{-1/2}),
\]

when \( p \neq q \). Indeed, we have

\[
\mathbb{E}(W_n) = \Theta(nL_n^{-1/2}).
\]

The upper bound can be proved by applying the arguments used in [16], which start from the inequality

\[
\mathbb{E}(W_n) \leq \mathcal{M}_n + \sum_{|k - L_n/h| \leq \varepsilon L_n^{2/3}} \frac{\mathbb{V}(I_{n,k})}{\mathcal{M}_n - \mathbb{E}(I_{n,k})} + \sum_{|k - L_n/h| > \varepsilon L_n^{2/3}} \mathbb{E}(I_{n,k}),
\]

where \( \mathcal{M}_n := \max_k \mathbb{E}(I_{n,k}), \) and then using the asymptotics of \( \mathbb{E}(I_{n,k}) \) and \( \mathbb{V}(I_{n,k}) \) given in section 6.1. Details are omitted here. Finer results for \( \mathbb{E}(W_n) \) can be derived, but the proof is more involved due to the presence of the periodic function \( G_3 \) (whose parameter involves \( k \)).

For symmetric tries, we easily have \( \mathbb{E}(W_n) = \Theta(n) \), by (93) and the trivial bound \( \mathbb{E}(W_n) \leq n \). Thus random symmetric tries are “fatter,” and most nodes lie near the most abundant levels \( k = \log_2 n + \mathcal{O}(1) \).

**Height.** We next derive an estimate for the height of random tries, as a consequence of our estimates for the external profiles together with the use of the first and second moment methods (see [79]).

**Corollary 6** (height of a trie). Let \( H_n := \max\{k : B_{n,k} > 0\} \) be the height of a random trie. Then \( H_n / \log n \to \alpha_3 \) in probability.
Proof. Let \( k_H := \alpha_3 L_n \). First we derive an upper bound for \( H_n \) as follows:

\[
\mathbb{P}(H_n > (1 + \varepsilon)k_H) \leq \mathbb{P}(B_{n,k} \geq 1) \text{ (for some } k \geq (1 + \varepsilon)k_H) \leq E(B_{n,k}) \rightarrow 0,
\]

where the last inequality follows from Theorem 3 when \( p \neq q \) and (91) when \( p = q \). For the lower bound, we use the second moment method (see [79]) to find

\[
\mathbb{P}(H_n < (1 - \varepsilon)k_H) \leq \mathbb{P}(B_{n,\lceil (1 - \varepsilon)k_H \rceil} = 0) \leq \mathbb{V}(B_{n,\lceil (1 - \varepsilon)k_H \rceil}) \leq \frac{1}{(E(B_{n,\lceil (1 - \varepsilon)k_H \rceil}))^2} = O\left(\frac{1}{E(B_{n,\lceil (1 - \varepsilon)k_H \rceil})}\right) \rightarrow 0
\]

by Theorems 3 and 7 and (94). Combining the two estimates, we obtain the required result.

Corollary 6 is not new and has already been derived in Devroye [12], Pittel [64, 65], and Szpankowski [77].

Shortest path. The shortest path \( S_n := \min\{j : B_{n,j} > 0\} \) of a random trie, discussed next, has attracted much less attention than the height (see [79]) in the literature. It is closely related to the behaviors of the external profile in range (I) near \( k = \alpha_1(L_n - LLLn + O(1)) \) as discussed in Theorem 1 and its refinement in Corollary 3.

Define

\[
\hat{k} := \begin{cases} 
\alpha_1 (L_n - LLLn - \log m_0 + m_0 \log(p/q) - \frac{LLL_n}{m_0LL_n}) & \text{if } p \neq q, \\
\alpha_1 (L_n - LLL_n) & \text{if } p = q,
\end{cases}
\]

where \( m_0 := \lceil 1/(p/q - 1) \rceil \), and

\[
k_S := \begin{cases} 
\lceil \hat{k} \rceil & \text{if } p \neq q, \\
\lfloor \hat{k} \rfloor & \text{if } p = q.
\end{cases}
\]

**Corollary 7** (shortest path length of tries). If \( p \neq q \), then

\[
S_n = \begin{cases} 
k_S & \text{if } \{\hat{k}\}LLn \rightarrow \infty, \\
k_S or k_S - 1 & \text{if } \{\hat{k}\}LLn = O(1)
\end{cases}
\]

with high probability;\(^2\) if \( p = q = 1/2 \), then

\[
S_n = \begin{cases} 
k_S + 1 & \text{if } \{\hat{k}\}L_n \rightarrow \infty, \\
k_S or k_S + 1 & \text{if } \{\hat{k}\}L_n = O(1)
\end{cases}
\]

with high probability.

**Proof.** Assume \( p \neq q \). Consider first the case \( \{\hat{k}\}LLn \rightarrow \infty \). In this case we have, by Corollary 3,

\[
\begin{align*}
\mu_{n,k_S} & \rightarrow \infty, \\
\mu_{n,k} & \rightarrow 0 \text{ for } k \leq k_S - 1.
\end{align*}
\]

\(^2\) We say that an event holds with high probability if it holds with probability tending to 1 as \( n \rightarrow \infty \).
Thus, again by the second moment method,
\[ P(S_n > k_S) \leq P(B_{n,k_S} = 0) \leq \frac{\text{Var}(B_{n,k_S})}{(\mathbb{E}(B_{n,k_S}))^2} = O\left(\frac{1}{\mu_{n,k_S}}\right) \to 0. \]

On the other hand, by using the first moment method, we have
\[ P(S_n < k_S) \leq P(B_{n,k} \geq 1) \text{ (for some } k < k_S) \leq \mu_{n,k} \to 0. \]

These two estimates imply that \( P(S_n = k_S) \to 1. \)

Now if \( \{\hat{k}\}L_n = O(1), \) then, again by Corollary 3,
\[ \mu_{n,k_S} \to \infty, \quad \mu_{n,k_S - 1} = \Theta(1), \quad \mu_{n,k} \to 0 \text{ for } k \leq k_S - 2. \]

Thus applying mutatis mutandis the same proof gives
\[ P(S_n = k_S) + P(S_n = k_S - 1) \to 1. \]

The proof for the symmetric case is similar, because \( \mu_{n,k} \to \infty \) when \( k \) lies in the range (95), and from this result we deduce that \( \mu_{n,k_S + 1} \to \infty, \mu_{n,k_S - 1} \to 0, \) and
\[ \mu_{n,k_S} \begin{cases} \to 0 & \text{if } \{\hat{k}\}L_n \to \infty, \\ = \Theta(1) & \text{if } \{\hat{k}\}L_n = O(1). \end{cases} \]

This completes the proof. \[ \square \]

**Fill-up level.** We now consider the fill-up level \( F_n = \max\{k : I_{n,k} = 2^k\} \) of a random trie, which was also analyzed previously by Devroye [12], Pittel [64, 65], and Knessl and Szpankowski [49].

**Corollary 8 (fill-up level of a trie).** If \( p \neq q, \) then
\[ F_n = \begin{cases} k_S - 1 & \text{if } \{\hat{k}\}L_n \to \infty, \\ k_S - 2 \text{ or } k_S - 1 & \text{if } \{\hat{k}\}L_n = O(1) \end{cases} \]

with high probability; if \( p = q = 1/2, \) then
\[ F_n = \begin{cases} k_S & \text{if } \{\hat{k}\}L_n \to \infty, \\ k_S \text{ or } k_S - 1 & \text{if } \{\hat{k}\}L_n = O(1). \end{cases} \]

**Proof.** Observe that
\[ F_n = \max\{k : \bar{I}_{n,k} = 0\} = \min\{k : \bar{I}_{n,k} > 0\} - 1. \]

By (86), we have \( \mathbb{E}(\bar{I}_{n,k}) \sim \mu_{n,k} \) when \( k \leq \alpha_1(1 + o(1))L_n. \) Thus the proof of Corollary 7 applies with little modification. \[ \square \]

**Profile enumerating only right branches.** We consider the random variable \( R_{n,k}, \) which denotes the number of external nodes in random tries that are away from the root by \( k \) right branches. Since a right branch means a “1” in the input-string, \( R_{n,k} \) enumerates the number of strings with exactly \( k \) 1’s; it also has other concrete interpretations in splitting processes and conflict resolution algorithms. All of our
tools can be extended to $R_{n,k}$, although $R_{n,k}$ exhibits very different behaviors. For example, unlike $B_{n,k}$ or $I_{n,k}$, there is no need to distinguish between symmetric and asymmetric tries, all results being uniform in $p$; also, the Poisson heuristic holds for all $k \geq 0$. This example further reveals the power of our approaches.

The probability generating function $F_{n,k}(y) := \mathbb{E}(y^{R_{n,k}})$ of $R_{n,k}$ satisfies the recurrence

$$F_{n,k}(y) = \sum_{0 \leq j \leq n} \binom{n}{j} p^j q^{n-j} F_{j,k-1}(y) F_{n-j,k}(y) \quad (n \geq 2; k \geq 0),$$

with the initial conditions $F_{n,k}(y) = 1$ for $n \leq 1$ or $k < 0$ and $F_{2,1}(y) = y$. Thus the bivariate generating function $F_k(z,y) := \sum_n F_{n,k}(y) z^n / n!$ satisfies

$$F_k(z,y) = F_k(qz,y) F_{k-1}(pz,y) = \prod_{j \geq 0} F_0(p^j q^j z, y)^{(k+j-1)},$$

where

$$F_0(z,y) = e^{pz} F_0(qz,y) + p(1-p/2)(y-1)z^2,$$

which is further solved to be

$$F_0(z,y) = e^z + p(1-p/2)(y-1) \sum_{j \geq 0} (q^j z)^2 e^{(1-q^j)z}.$$

From this we deduce that the expected right-profile is given by

$$\mathbb{E}(R_{n,k}) = \mathbb{E}(p(1-p/2)n! \left[\sum z^n \frac{e^z}{2\pi i} \int_{(\rho)} z^{-s} \Gamma(s + 2) \frac{p^{-ks}}{(1-q^{-s})^{k+1}} \, ds\right],$$

where $-2 < \rho < 0$. The integral is not of the same type as (6) but is similar, and our methods of proof easily extend. It has simple poles at $s = -2, -3, \ldots$ and poles of order $k+1$ at $s = 2j\pi i / \log(1/q)$, $j \in \mathbb{Z}$. Thus the asymptotics of $\mathbb{E}(R_{n,k})$ are divided into four overlapping ranges.

- If $0 \leq k = o(\log n)$, then the residues of the poles on the imaginary lines are dominant, and we have

$$\mathbb{E}(R_{n,k}) \sim p(1-p/2) \frac{(\log p^k n)^k}{k!(\log(1/q))^{k+1}} \left(1 + \sum_{j \neq 0} \Gamma(1 + \chi_j)(p^k n)^{-\chi_j}\right),$$

uniformly in $k$, where $\chi_j := 2j\pi i / \log(1/q)$.

- If $k \to \infty$ and $k \leq \alpha^*(L_n - K_n \sqrt{L_n})$, where $K_n \to \infty$ and

$$\alpha^* := \frac{1 - q^2}{(1 - q^2) \log(1/p) - q^2 \log(1/q)},$$

then by the saddle-point method

$$\mathbb{E}(R_{n,k}) \sim \frac{p(1-p/2)q^{p/2}}{\sqrt{2\pi k \log(1/q)}} (p^k n)^{-p} (1 - q^{-p})^{-k} \sum_{j \in \mathbb{Z}} \Gamma(p + 1 + \chi_j)(p^k n)^{-\chi_j},$$

uniformly in $k$, where

$$\rho = \log_{1/q} \frac{\log(p^k n)}{\log(p^k n / q^k)}.$$
where $\tau$ axis. This yields, by a straightforward modification of our approaches, that

$$\mathbb{E}(R_{n,k}) \sim \frac{1}{2} \Phi(x)(p^k n)^2 (1 - q^2)^{-k},$$

uniformly for $x = o(L_n^{1/6})$.

- If $k \geq \alpha^* L_n + K_n \sqrt{\alpha^*(1 + \alpha^* \log(p/q))(1 + \alpha^* \log p)L_n}$, then

$$\mathbb{E}(R_{n,k}) \sim \frac{1}{2}(p^k n)^2 (1 - q^2)^{-k}.$$

These results imply that, as $n \to \infty$, $\mathbb{E}(R_{n,k}) \to \infty$ iff

$$1 \leq k \leq \frac{2}{\log \frac{2L_n}{p}} L_n - K_n,$$

where $K_n \to \infty$ with $n$. Note that

$$\log e^{-z} \mathcal{F}_0(z, y) = \log(1 + (y - 1)\tau(z)),$$

where $\tau(z) := p(1 - p/2) \sum_{j \geq 0} (q^j z)^j e^{-q^j z}$ satisfies $\tau(z) = O(|z|^2)$ as $z \to 0$, and, by Mellin transform, $\tau(z) = \tilde{O}(1)$ as $|z| \to \infty$ in a small sector containing the real axis. This yields, by a straightforward modification of our approaches, that $\nabla(R_{n,k}) = \Theta(\mathbb{E}(R_{n,k}))$ for all $k = k(n) \geq 0$ and that

$$\frac{R_{n,k} - \mathbb{E}(R_{n,k})}{\sqrt{\mathbb{V}(R_{n,k})}} \xrightarrow{d} \mathcal{N}(0, 1)$$

whenever $\mathbb{E}(R_{n,k})$ or $\nabla(R_{n,k}) \to \infty$. Two remaining cases are $k = 0$ and $k = 2L_n/\log \frac{2L_n}{p} + O(1)$. In the first case, $R_{n,0}$ by (98) is Bernoulli distributed with mean equal to $\tau(n)$, which is asymptotic to the periodic function

$$\frac{1}{\log(1/q)} \left( 1 + \sum_{j \neq 0} \Gamma(2 - \chi_j)n^{-\chi_j} \right),$$

and in the second case,

$$\mathbb{P}(R_{n,k} = m) = \frac{\lambda_3^m}{m!} e^{-\lambda_3} + o(1),$$

where $\lambda_3 := (p^k n)^2 (1 - q^2)^{-k}/2$.

**Appendix A: Proof of Lemma 3.** In this appendix, we prove Lemma 3. For part (i) let $z = ne^{i\theta}$, where $\theta = o(LL_n^{-1/2})$. By (8)

$$\tilde{M}_k(z) = \sum_{0 \leq j < k} \binom{k - 1}{j} p^j q^{k-j} z e^{-p^j q^{k-j} z} \left( 1 + O \left( e^{-i(p-q)p^j q^{k-j} n \cos \theta} \right) \right)$$

$$= \sum_{0 \leq j < k} \binom{k - 1}{j} p^j q^{k-j} z e^{-p^j q^{k-j} z} \left( 1 + O \left( e^{-i(p-q)p^j q^{k-j} n \cos \theta} \right) \right)$$

(99)

$$= q^k z e^{-q^k z} \left( 1 + O(E_0) \right),$$

where $E_0$ is the contribution from the term $z = ne^{i\theta}$.

- If $k = \alpha^* L_n + \alpha^* \log(p/q)(1 + \alpha^* \log p)L_n$, then

$$\mathbb{E}(R_{n,k}) \sim \frac{1}{2} \Phi(x)(p^k n)^2 (1 - q^2)^{-k},$$

uniformly for $x = o(L_n^{1/6})$.
where

\[ E_6 := \sum_{1 \leq j < k} \frac{(p \alpha_1/q)^j}{j!} L_n^{-j} e^{-(q/p) j^2/n} \cos \theta. \]

Since \(1 \leq k \leq k_0 - \alpha_1 K_n/LL_n\), we have

\[ q^k n \geq \frac{LL_n}{p/q - 1} e^{K_n/LL_n}. \]

It follows, by using the inequality

\[ \frac{t^j - 1}{t - 1} \geq j \quad (t > 1; j \geq 1), \]

that

\[ E_6 \leq \sum_{j \geq 1} \frac{(p \alpha_1/q)^j}{j!} L_n^{-j} e^{-j \cos \theta} e^{K_n/LL_n} \]

\[ \leq \sum_{j \geq 1} \frac{(p \alpha_1/q)^j}{j!} L_n^{-j \cos \theta} e^{K_n/LL_n} \]

\[ \leq \sum_{j \geq 1} \frac{(p \alpha_1/q)^j}{j!} e^{-j K + O(j \theta^2 LL_n)} \]

\[ = O(e^{-K_n}), \]

since \(\theta = o(LL_n^{-1/2})\). This proves (30).

For part (ii), by (99),

\[ \tilde{M}_k(z) = S_{k,m}(z) \left( 1 + O \left( e^{-(p-q)p^m q^{k-m} n \cos \theta} + E_7 + E_8 \right) \right), \]

where

\[ E_7 := \sum_{0 \leq j < m} \left| \frac{S_{k,j}(z)}{S_{k,m}(z)} \right| \left( 1 + O \left( e^{-(p-q)p^m q^{k-m} n \cos \theta} \right) \right), \]

\[ E_8 := \sum_{m < j < k} \left| \frac{S_{k,j}(z)}{S_{k,m}(z)} \right| \left( 1 + O \left( e^{-(p-q)p^m q^{k-m} n \cos \theta} \right) \right). \]

By (31), \(p^m q^{k-m} n = e^\eta LL_n/(p/q - 1)\). It follows, by changing \(j\) to \(m - j\), that

\[ E_7 = O \left( m \sum_{1 \leq j \leq m} \frac{(q/p)^j}{(m-j)!} k^{-j} \exp \left( p^m q^{k-m} n \cos \theta \right) \right) \]

\[ = O \left( m \sum_{1 \leq j \leq m} \frac{(q/p)^j}{(m-j)!} L_n^{-j} e^{\eta \cos \theta} \right) \]

\[ = O \left( m \sum_{1 \leq j \leq m} \frac{(q/p)^j}{(m-j)!} L_n^{-j} e^{(1-\eta \cos \theta/p)} \right) \]

\[ = O \left( m e^{K_n} \right) = O(\eta e^{K_n}), \]

since \(\eta \leq \log(p/q) - K_n/LL_n\) and \(\theta = o(LL_n^{-1/2})\).
By simple calculus, we have
\[ a(\text{as needed for the proof of Proposition 4).} \]

Lemma 8. Let \( f(z) \) be an entire function satisfying

\[ f(z) = \begin{cases} O(|z|^2) & \text{as } z \to 0, \\ O(|z|e^{-\rho(z)}) & \text{as } z \to \infty, \arg(z) \leq \bar{\varepsilon}, \end{cases} \]

Similarly,
\[
E_8 = O \left( m! \sum_{j \geq m} \frac{(p/q)^{j-m}}{j!} k^{j-m} \exp \left( -p^m q^{k-m} n \cos(\theta) \left( (p/q)^{j-m} - 1 \right) \right) \right)
\]
\[
= O \left( m! \sum_{j \geq 1} \frac{(p\alpha_1/q)^j}{(j+m)!} L_n^{j-(p/q)^{j-1}} e^{\eta \cos \theta} \right)
\]
\[
= O \left( m! \sum_{j \geq 1} \frac{(p\alpha_1/q)^j}{(j+m)!} L_n^{-j (e^{-\eta \cos \theta}-1)} \right)
\]
\[
= O \left( m^{-1} L_n^{-\eta (e^{-\eta \cos \theta}-1)} \right) = O \left( m^{-1} e^{-K_n} \right)
\]

since \( \eta \geq K_n/LL_n \). This completes the proof of (32). □

Appendix B: Well-definedness of \( Q_k(z, y) \). We prove here the following lemma that is needed for the proof of Proposition 4.

Lemma 7. The function \( Q_k(re^{i\theta}, y) \) is well defined for \( r \geq 0, |\theta| \leq \varepsilon \), and \( |y| = 1 \).

Proof. We first show that

\[ |a_3(r)(e^{i\varphi} - 1) + a_4(r)(e^{i\varphi} - 1)^2| < 1 \]
for \( r \geq 0 \) and \( |y| = 1 \). By direct calculation, we have
\[
|a_3(r)(e^{i\varphi} - 1) + a_4(r)(e^{i\varphi} - 1)^2|^2 = a_3(r)^2 |e^{i\varphi} - a_3(r) - a_4(r)v|^2
\]
where \( v := 2(1 - \cos \varphi) \). Since
\[
a_3(r) - a_4(r) \geq a_3(r) - 2a_4(r) = e^{-r} (pr(e^{qr} - 1 - qr) + qr(e^{qr} - 1 - pr)) \geq 0,
\]
we have
\[
|a_3(r)(e^{i\varphi} - 1) + a_4(r)(e^{i\varphi} - 1)^2| \leq \sqrt{2} a_3(r).
\]

By simple calculus, we have \( a_3(r) < 2^{-1/2} \), which implies (100). Indeed, the inequality \( a_3(r) < 2^{-1/2} \) is equivalent to
\[
pre^{-pr} + qre^{-qr} - re^{-r} < 2^{-1/2} \quad (r \geq 0),
\]
and we have
\[
pre^{-pr} + qre^{-qr} - re^{-r} \leq \max_{r \geq 0} re^{-r}(e^{r/2} - 1) \approx 0.52 < 2^{-1/2}.
\]

This proves the lemma when \( z = r \); then the assertion of the lemma follows from analyticity. □

Appendix C: A useful approximation. In the proof of Proposition 4 we need the following lemma.

Lemma 8. Let \( f(z) \) be an entire function satisfying

\[ f(z) = \begin{cases} O(|z|^2) & \text{as } z \to 0, \\ O(|z|e^{-\rho(z)}) & \text{as } z \to \infty, \arg(z) \leq \bar{\varepsilon}, \end{cases} \]
where \( \varepsilon > 0 \). Then, uniformly for all \( k = k(n) \geq 1 \) and \( z = ne^{i\theta}, |\theta| \leq \varepsilon \),
\[
f_k(z) := \sum_{0 \leq j < k} \binom{k-1}{j} f(p^j q^{k-1-j} z) = \Theta(\bar{M}_k(z)).
\]

**Proof.** If \( 1 \leq k \leq k_0 \), then it is easy to see that \( f_k(z) = \Theta(\bar{M}_k(z)) \) for \( |\theta| \leq \varepsilon \). When \( k \geq k_0 \), let \( f^*(s) := \int_0^\infty x^{s-1} f(x) dx \). Then \( f^*(s) \) is well defined in the half-plane \( \Re(s) > -2 \) by (101). By the estimates in (101) and the same argument used in [23, Proposition 5], we have, assuming \( \rho \geq 1 \) and \( t > 0 \),
\[
f^*(\rho + it) = \int_0^{e^{i\varepsilon}} x^{\rho+it-1} f(x) dx
\]
\[
= e^{i\varepsilon(\rho+it)} \int_0^\infty x^{\rho+it-1} f(x e^{i\varepsilon}) dx
\]
\[
= O(e^{-\varepsilon t} \int_0^1 x^{\rho+1} dx) + O \left( e^{-\varepsilon t} \int_0^\infty x^\rho e^{-qx\cos \varepsilon} dx \right)
\]
\[
= O \left( e^{-\varepsilon t} \rho^{-1} + e^{-\varepsilon t} q^{-\rho^{1/2}(\rho/e)^\rho} \right),
\]
uniformly in \( \rho \) and \( t \). If \( t < 0 \), then changing \( e^{i\varepsilon} \) to \( e^{-i\varepsilon} \) gives
\[
f^*(\rho + it) = O \left( e^{-\varepsilon|t|} \rho^{-1} + e^{-\varepsilon|t|} q^{-\rho^{1/2}(\rho/e)^\rho} \right).
\]
When \(-2 < \rho \leq 1\), \( f^*(\rho + it) = O(e^{-\varepsilon|t|}) \) for large \( |t| \) by the same argument. On the other hand, by the first estimate in (101), we also have
\[
f^*(s) = O \left( |s + 2|^{-1} \right) \quad (s \to 2).
\]

With these estimates and the Mellin inversion integral
\[
f_k(z) = \frac{1}{2\pi i} \int_{(\rho)} z^{-s} f^*(s) (p^{-s} + q^{-s})^{k-1} ds,
\]
we can apply the arguments used for \( \bar{M}_k(z) \) and prove that \( f_k(z) = \Theta(\bar{M}_k(z)) \) for \( |\arg(z)| \leq \varepsilon \). \( \Box \)
